Notes. These data apply when the capacitor is connected at the motor terminals.

\* Representative data for 3-phase, 60-cycle, general-purpose, or splashproof-type motors of 220, 440, or 2300 volt rating. For 50-cycle application the following representative data may be used:

(1) For standard 60-cycle motors operating at 50 cycles, multiply kvar from table by 1.3. Multiply per cent AR from table by 1.1.

(2) For standard 50-cycle motors operating at 50 cycles, multiply kvar from table by 1.1. Multiply per cent AR from table by 1.0.

The operating power factor, with capacitor ratings listed in these tables, ranges from 95 to 98% at full load and from 95 to 100% at partial loads.

† Kvar is rating of capacitors in kilovolt-amperes.

‡ % AR is percentage reduction in line current due to capacitors and is helpful for selecting the proper motor-overload relay.

**COST COMPARISON OF INDUCTION MOTORS AND CAPACITORS VERSUS SYNCHRONOUS MOTORS.** Initial cost is the most important guide in making the selection between the induction motor plus capacitors and the synchronous motor. The following tables show motor rating ranges where the cost of an induction motor plus capacitors (including a separate switching device for the capacitors) is less than an 0.8 pf synchronous motor and starter.

**440- and 550-volt Equipment.**

Motor Speed, rpm	Motor Rating, hp
1800	250 and less
1200	150 and less
900	150 and less
600	200 and less

**2300-volt Motor and Control Equipment with 460- or 575-volt Capacitors.** (Capacitors should be located on the 460- or 575-volt utilization systems rather than 2400- or 4160-volt systems for maximum overall benefit.)

Motor Speed, rpm	Motor Rating, hp
1800	250 and less
1200	175 and less
900	175 and less
600	200 and less

**2300-volt Equipment.** The synchronous motor and starter equipment costs less than the induction motor and capacitor combination over the entire speed range if a power circuit breaker is used to switch the capacitors.

For the above comparisons, the capacitor rating was selected on the basis that the induction-motor and capacitor combination will furnish the same amount of power-factor improvement at full load as an 0.8 power-factor synchronous motor of equal rating. At partial-load operation, the synchronous motor can supply slightly more kilovars to the system than the induction motor plus capacitor combination, but the difference is not great enough to be the basis of selection.

From the standpoint of total losses the two methods are a standoff. However, where efficiency is carefully evaluated individual comparisons should be made.

Fig. 38. Effect of capacitors on induction motor power factor.

Fig. 39. Synchronous motor kilovars versus load at rated excitation.

**POWER-FACTOR IMPROVEMENT FROM SYNCHRONOUS MOTORS.** Synchronous motors may act as kilovar generators, and they generate kilovars in the same manner as a conventional generator does. Their ability to generate kilovars is a function of excitation and load. When underexcited they may not generate sufficient kilovars to supply their own needs and consequently must take additional kilovars from the system. When overexcited (normal operation), they can supply all their own kilovar requirements, and in addition can supply kilovars to the system. Thus they may be operated as kilovar generators. The curves of Fig. 39 show the kilovars that a synchronous motor is capable of delivering under various load conditions with normal excitation. As load increases, the number of kilovars the motor can supply decreases. At high overloads (not shown on these curves) a synchronous motor will take magnetizing current from the line.

**MAXIMUM CAPACITOR RATING FOR GENERATORS.** When generators are operated at leading power factor or underexcited, i.e., with less than normal excitation (as when too many kilovars are supplied by capacitors or synchronous motors), the generator will be unstable so that the prime mover pulls out of step and is unable to maintain voltage.

Figure 40 shows the approximate maximum kilovars for leading power-factor operation of generators for solid rotor (turbine-type) generators, and also for salient pole (engine-type) generators. Note that the kilovar and kilowatt values are in percentage of the generator *kva*-rating. These data are approximate—there are too many variables to consider to be more specific. They serve as a useful guide, however, in establishing the maximum amount of unswitched capacitors.

**LOCATION OF CAPACITORS.** All the benefits that capacitors provide stem from the reduction of kilovar flow. This is true of power bill savings, release of system capacity, voltage improvement, and reduction of

Maximum reduction in kilovar flow is obtained when capacitors are located at the load. The concept of capacitors as kilovar generators is particularly helpful in understanding this point.

FIG. 40. Maximum kilovar output of generators. Data applicable to modern generators of normal design operated with voltage regulators. Curve A is for salient pole (engine-type) generators. Curve B is for round rotor (turbine-type) generators.

FIG. 41. Best location of capacitors. Order of preference:  $C_1$ ,  $C_2$ ,  $C_3$ ,  $C_4$ .

Although maximum overall benefit is obtained when capacitors are located at the load, it is not always practical or economical to locate capacitors at each load. Whenever possible capacitors should be located near the load on 460- or 575-volt systems to obtain minimum cost and maximum benefits. These locations are shown in Fig. 41. The most desirable location is at the load as shown by  $C_1$ ; next  $C_2$ , etc.

## SUBSTATIONS \*

An electric power substation is a grouping of electrical equipment through which electric energy is passed for the purpose of switching or of transforming voltage levels. Installations including generation or utilization equipment or minor distribution or transmission equipment are not usually classified as substations.

The general classification includes *primary substations* and *secondary substations*. A primary substation is defined as a substation having a low-side voltage between 601 and 15,000 volts. A secondary substation is one having a low-side voltage of 600 volts or less.

### 17. PRIMARY SUBSTATIONS

Primary substations provide the connecting link between transmission or subtransmission circuits and distribution circuits. They may be located outdoors, adjacent to the industrial plant, or only the high-voltage switchgear and transformers may be located outside the building and connected to indoor low-voltage switchgear by metal-enclosed bus passing through the building wall. In another arrangement, the entire primary substation is located outdoors whereas metering devices, relays, and control switches for the power circuit-breakers are located indoors on a central control panel. Factors that affect the arrangement selection are:

- (1) Comparative value of space indoors and outdoors.
- (2) Difference in the cost of weatherproof and indoor-type switchgear.

\* Contributed by J. W. Yetter and L. D. Madsen.

- (3) Frequency of operation of the power breakers and various other circuit elements.
- (4) Prevailing weather conditions that may influence the desirability of operating outdoor installations.
- (5) Presence of corrosive, dusty, or otherwise unsuitable atmospheres that may be encountered with some industrial processes.
- (6) Local building codes and regulations.

A typical outdoor primary substation (Fig. 42) consists of *high-voltage switching equipment*, *transformers*, and *low-voltage metal-clad switchgear*. A description of these three components is given in the following paragraphs.

Fig. 42. Typical primary substation.

**HIGH-VOLTAGE SWITCHING EQUIPMENT.** For voltages above 15 kv, switchgear consisting of *outdoor circuit-breakers*, *disconnecting switches*, *lightning protective equipment*, *fuses*, and *open-type bus* are normally used. These elements are mounted on or within a steel structure. Incoming circuits are terminated on the structure by means of strain insulators. Outdoor power circuit-breakers for stationary service are available in voltage ratings of 7.5 kv and above. Interrupting ratings vary with voltage and range from 50,000 kva to 10,000,000 kva. These breakers are usually of the oil-filled tank type with a single mechanism for three-pole operation. They are provided with their own means of support so that they may be mounted on a concrete pier within the main substation structure.

**Disconnecting switches** mounted on porcelain insulators in the station structure may be of the *group-operated* or *hook-operated* type. Group-operated switches are somewhat more expensive but are usually preferred because they permit indirect operation either manually or by motor mechanisms. Hook-operated switches are commonly used with fuses or as unfused switches for single-phase

devices such as lightning arresters, and potential and control transformers. It is usual practice to apply group-operated isolating switches with stationary-mounted power circuit-breakers ahead of power transformers. Although disconnecting switches have no published interrupting rating, it is recognized that they have certain limited interrupting ability. Group-operated switches equipped with arcing horns are frequently used at lower voltages to interrupt transformer exciting current, line charging current, and, in some cases, small load currents. For breaking load, heavy line-charging current, or exciting current of large transformers, particularly at the higher voltages, a power circuit-breaker is used.

Fig. 43. Cones of protection provided by lightning masts or ground wires.

Where transformers are too small to justify individual high-voltage breakers, power fuses are frequently employed to remove a faulted circuit element from the system. These fuses should be chosen to provide adequate protection, should be rated to pass transformer magnetizing inrush currents, and should coordinate with low-voltage circuit-breaker relaying.

**Surge Protection.** Outdoor substations are provided with protection from both direct strokes and voltage surges arriving over transmission lines. Direct stroke protection is afforded by lightning masts extending above the substation structure as shown by Fig. 43 or by overhead ground wires. Direct stroke protection should be designed so that all substation equipment is included within protective cones around the masts and/or ground wires. The protective cone should have angles not greater than those shown in Fig. 43.

The best protection against incoming surges is provided by lightning arresters. The type of arrester used depends primarily on the voltage of the circuit. The types available are: (1) station-type, 3 kv to 300 kv; (2) line-type, 20 kv to 73 kv; (3) distribution-type, 1 kv to 15 kv.

The station-type arrester affords a better protective level and has a higher discharge capacity than either of the other types. When the importance of equipment does not justify the expense of the station type arrester, the distribution or line types may be used.

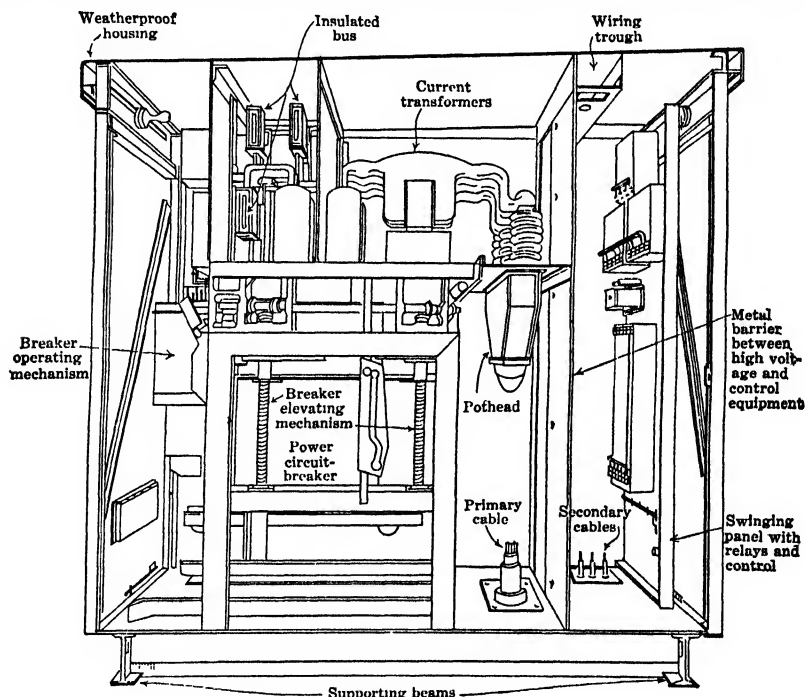

Fig. 44. Side view of typical metal-clad feeder breaker compartment.

The arrester should be located as close as possible electrically to the protected equipment. The arresters also should be located to protect normally open disconnecting switches or circuit-breakers.

**POWER TRANSFORMERS** integrally connected to metal-enclosed switchgear are of the three-phase type. Oil-filled transformers are used outdoors. Where power transformers are installed indoors, a noninflammable askarel-type insulating and cooling liquid is used. When relative location of transformers and switchgear permits, connections between components are made through a metal enclosure. This may be a direct connection, as shown in Fig. 42, or a length of metal-enclosed bus. In the latter case the transformers and switchgear may be separated by a building wall. In other arrangements, cable is used to connect transformer and switchgear. Incoming line connections to the transformer may be to cover-bushings or by means of cable to a junction box or switch box on the end of the tank. Outgoing connections are through bushings in the end of the tank to the switchgear, bus, or cable junction box. Standard substation transformers of the ratings normally used for industrial plants are listed in Table 24.

Where regulated primary feeders are required, transformers are available in listed ratings with self-contained automatic step-voltage regulators having a range of  $\pm 10\%$ .

Table 24. Ratings of Standard Power Transformers

The voltage maintained is a function of load current. This equipment is commonly called *load-ratio control equipment*.

**LOW-VOLTAGE SWITCHING EQUIPMENT.** For 15 kv and below, switching equipment may be of the open type described above or of the completely metal-enclosed factory-assembled type. Nearly all modern installations employ the latter type. An interior perspective view of a typical metal-clad feeder section is shown in Fig. 44. A typical installation includes several of these feeder compartments together with auxiliary compartments necessary to house control power and potential transformers, tripping, battery and charger, and associated accessory devices. Features of the metal-enclosed construction include separate compartments for the insulated bus, power circuit-breaker, relaying and control panel, current transformers, and the incoming cable. The power circuit-breakers are either of the vertical-lift type, as illustrated, or of the horizontal-drawout type, to make the breakers easily removable. Isolation from the circuit is accomplished without disconnecting switches. Power circuit-breakers are available in ratings shown in Table 25.

Metal-clad switchgear rated 5 or 15 kv is applicable for the high-voltage or low-voltage circuits of primary substations or as incoming line sections to secondary substations.

## 18. SECONDARY SUBSTATIONS

Secondary substations provide the connecting link between distribution circuits and utilization equipment. Standard secondary voltage ratings are 208Y/120, 240, 480, and 600 volts.

Secondary substations consist of incoming line sections, transformers, and low-voltage switchgear. These sections are usually joined to form an integral unit. A typical secondary substation including incoming liquid-filled switches, askarel transformers, and metal-enclosed drawout switchgear is illustrated in Fig. 45.

Fig. 45. Typical double-ended load center unit substation.

**INCOMING LINE SECTIONS** may be (1) metal-clad switchgear; (2) switch and fuse; (3) interrupter switch; (4) cable junction box; and (5) cover bushings.

Metal-clad switchgear, described under Primary Substations, Art. 17, can be directly connected on the high-voltage side of the transformer. This equipment has one or more transformer primary circuit-breakers and necessary auxiliary equipment. Power company metering equipment, if required, may be included.

Where necessary, the incoming section of each may consist of an interrupter switch and fuses. The fuses are supplied to remove automatically a faulted unit from the primary circuit. (See Art. 12.) The switch provides manual disconnection of a unit without interruption of service to the remaining units.

When suitable fault protection is afforded by a primary feeder breaker and an interruption of service to other substations on that circuit is not objectionable, the fuses are omitted and only the interrupter switch is furnished. This may be a liquid-filled or an air switch, depending on the type and kva rating of the transformer with which it is used. The interrupter switch is mechanically interlocked with the low-voltage main breaker to prevent its operation under load.

In simple radial distribution systems, junction boxes arranged to terminate one or more primary cables may be all that is required. At 15 kv and below, these junction boxes are usually air filled.

For outdoor installations, particularly at the higher voltages, the transformers may be equipped with cover bushings for the incoming lines.

**TRANSFORMERS.** Transformers for use in secondary substations may be of the liquid-filled or air type. Oil-filled transformers are used in those few installations made outdoors. Most secondary substations are installed indoors, and to avoid the expense of

Table 26. Ratings of Transformers for Secondary Substations

Item	Low Voltage Rating	Preferred High-voltage Ratings *	Kva Ratings	Per Unit Impedance

	480 or 600	As in A	As in B, † plus 2000	As in B, † plus .055

\* Standard transformers have four 2 1/2% rated kva taps in the high-voltage windings, two above and two below rated primary voltage.

† Except 100 kva not listed.

fireproof vaults askarel-filled or air-filled transformers are used. Three-phase transformers for use in secondary substations are available in ratings listed in Table 26. Increased capacity can be obtained by forced-air cooling. However, for the smaller ratings, it is usually more economical to purchase the next larger self-cooled rating than to add fans.

**OUTGOING FEEDER SWITCHGEAR.** Switchgear for 600 volts and lower is entirely enclosed in a grounded, dead-front metal structure, to permit installation of equipment in working areas without hazard to personnel. The assembly usually includes a transformer, main secondary breaker and feeder breakers, together with the necessary bus, current, and potential transformers, and meters and control devices. Where ungrounded shop circuits are used, an indicating ground detector is usually connected to the main bus and mounted on the front of the equipment.

The most frequently used arrangement employs breakers of the drawout (easily removable) construction. The breaker is mounted on a frame which rolls out or swings free of the structure. This drawout carriage is mechanically interlocked to prevent withdrawing the breaker from the connected position when it is closed. A test position is provided to permit operation of the breaker, inspection of the contacts, and general maintenance in the disconnected position without removing the breaker from the equipment. Double-pole and triple-pole drawout air circuit-breakers are available in ratings listed in Table 27.

Table 27. Ratings of Drawout Air Circuit-breakers

Current Interrupting Ratings, total rms amperes	Rating Continuous Rating, amperes	Voltage Rating	
		A-C	D-C
15,000	15 to 225	600	250
25,000	35 to 600	600	250
50,000	100 to 1600	600	250 and 750
75,000	2000, 3000	600	250 and 750
100,000	4000	600	250 and 750

In smaller ratings, breakers are available for either manual or electrical operation. Those having a continuous rating of 2000 amp or more are usually electrically operated because of their large size and the difficulty of closing them manually.

Air circuit-breakers are provided with inherent direct-acting trip devices which trip as a function of current when faults occur. The overcurrent trip usually consists of a time-delay portion, adjustable down to breaker rating or below, and an instantaneous portion set to operate without intentional time delay for currents of short-circuit magnitude. The most common time delay tripping device consists of a sealed dashpot filled with oil and a piston with a definite size orifice. Current through the breaker is used to excite an electromagnet that moves the piston causing the oil to flow through the orifice. The time required for the oil to flow determines the tripping time since the piston trips the breaker latch at the end of its stroke. This produces an inverse time-tripping curve (see Article 12). The short-circuit trip is a similar electromagnet arranged to overcome the force on a restraining spring above a predetermined value of current. For selective operation between breakers in series, an escapement timer is used to delay tripping of the breakers near the source.

**Cascade Operation.** In general, the interrupting rating of air circuit-breakers should equal or exceed the fault current obtainable at the location where the breakers are installed, 0.5 cycle after inception of the fault. Where may feeder breakers are served through one or two sources of power, it may be economically justifiable to use feeder breakers of reduced interrupting rating, provided they can be safely applied without too seriously impairing the required selectivity of tripping.

Cascaded or backed-up breakers are applied above their interrupting rating as follows:

- (1) All breakers connected directly to the incoming source must have interrupting ratings equal to the total fault current.
- (2) Provided that all breakers between it and the power sources are set to trip instantaneously at not more than 80% of the rating of the second breaker, the breaker in the cascade may be applied up to 200% of its interrupting rating.
- (3) Provided that the second breaker in cascade is set to trip instantaneously at not more than 80% of the rating of the third breaker, the third breaker in the cascade may be applied up to 300% of its interrupting rating. Further cascading cannot be done.

(Continued on p. 16-60)

\* Breaker 'A' selections are in all cases governed by the necessary continuous-current ratings of the transformer, and this is the reason that in some cases the interrupting ratings are higher than the ratings given for the corresponding 'A' breaker. Interrupting ratings of 'A' breakers are all based on the interrupting requirements only, as determined by the combined short-circuit total amperes.

- (4) No breaker, whether satisfying the conditions of 1, 2, and 3 or not, may be applied in any circuit where it may be called upon to open more than its interrupting rating without assistance of all other source breakers. In this respect, unusual conditions of load contribution to a fault must be carefully investigated. Unusually large (over 25%) synchronous motors, or a large percentage of synchronous loadings, will usually rule out cascade applications.

Where multiple-power sources are used, cascade rules usually dictate a very low instantaneous back-up setting. In direct contrast, multiple sources are usually employed to provide continuity of service under all conditions. A secondary selective system with tie circuits normally open often provides a better operating condition.

The principle of cascade operation depends on the back-up breakers operating with such speed that they assist the smaller breaker in interrupting the fault. For this reason, shunt trip coils operated by instantaneous relays are not satisfactory for back-up breakers. Furthermore, if a portion of the source current, but not all of it, is opened by back-up breakers, cascade cannot be used.

Application data for cascaded breakers are shown in Tables 28 and 29.

**Transformer secondary breakers** are usually selected with a continuous rating slightly above the transformer full-load current since transformers are required at times to carry loads in excess of their output rating.

**Breakers serving one or more motors** equipped with individual motor starters come under the general classification of motor branch feeder breakers. Their function is to disconnect the motor cables in case of fault. Motor overload and undervoltage protection are provided by the starter. The branch breakers may be equipped with standard inverse

\* The "full-load current" values are approximate and should be used for estimating purposes only. Application should always be based only on actual currents taken by the specific machines in the circuit. The breaker required should have rating between 115% and 140% of the actual, full-load current, or the next higher standard rating.

time trips. If a small number of motors is fed from a branch breaker, or if one of the motors is relatively large, long time delay trips are required to "ride over" the starting inrush. Where several small motors of the same relative size are served, a branch breaker equipped with standard trips may give enough time to allow the motors to be started without danger of tripping. In this case it is important that the motor starters be arranged to open on loss of voltage; otherwise the return of voltage after a momentary loss would draw starting current of the entire group of motors through the branch breaker.

Where a single breaker is used as a motor starter and protector, motor overload and undervoltage protection are required as well as cable protection. Thermal relays operated from current transformers will usually provide more accurate overload protection than direct-acting trips, and should always be used where the motor serves large or important loads. If thermal relays are used, the breaker can be equipped with short-circuit trips set to trip instantaneously at some value above the maximum starting inrush. When reliable tripping source is available, an undervoltage relay is preferred to direct-acting undervoltage device for motor protection.

Air circuit-breaker ratings for motor circuits are listed in Table 30. The recommended air circuit-breaker ratings include the 115% service factor standard for most a-c motors.

In addition to drawout switchgear, the secondary substation may include a section of motor control units—full-voltage, reduced-voltage, wound rotor, single- and multispeed and reversing starters grouped and interlocked in any sequence necessary for a particular process. Each starter unit consists of a contactor and some type of short-circuit protection. Short-circuit protection for the large motors is provided by a breaker backing up the contactor. A switch and fuse is used to back up contactors for smaller motors.

## SWITCHGEAR \*

**Definition.** Switchgear is a general term covering switching, interrupting, control, metering, protective and regulating devices, also assemblies of those devices with associated interconnections, accessories, and supporting structures for use in connection with the generation, transmission, distribution, and conversion of electric power.

**Selection of Switchgear.** In order to make a well-coordinated application of switchgear to any power system a one-line diagram of the system should be available. Such a diagram, together with information on maximum short-circuit currents at points of power entry, nature and ratings of loads, ratings and characteristics of transformers and generators, and the characteristics of power lines, gives a sound basis for the selection of suitable types and ratings of standard switchgear equipment.

**SYSTEM CHARACTERISTICS.** Available short-circuit current or kva evaluated at each point in the system where switchgear is to be used, determines the interrupting rating of the circuit-breakers or other circuit-interrupting devices used in the gear. Since standard gear is usually built with other parts designed to withstand the same or greater short-circuit currents than the breaker, gear having breakers of adequate interrupting ratings usually covers this phase of the selection.

**Voltage and frequency of the system** determine the general type of switchgear to be selected and the voltage rating within the type class.

**Maximum Load Requirement of Each Circuit.** From this information continuous ampere, kilowatt, kva, or horsepower ratings of the circuit units are determined.

**Service Requirements.** The degree of service continuity required for different circuits determines the type of circuit arrangement best suited to the application and, for low voltage circuits, the type of tripping system selected.

**Location of equipment** determines whether standard indoor, outdoor, drip-proof, or other type of switchgear enclosure is required. If there are unusual atmospheric conditions, such as the presence of explosive or corrosive gases, this should be called to the attention of the manufacturer.

**The Nature of the Various Loads.** From this information any unusual operating requirements can be determined, as for example the frequency with which circuit-breakers will be operated and under what conditions of load. Some types of load, such as electric-arc furnaces, require highly repetitive operation of the switchgear; the type of equipment required may differ from that used for less severe service. Manufacturers provide gear especially designed for such service.

**TYPES OF SWITCHGEAR.** Standardized types of switchgear equipment are available to meet a large percentage of the requirements of modern power systems, and leading

---

switchgear manufacturers are in a position to recommend the most advantageous modifications of such standard gear to meet other less frequently encountered situations. The salient features of these standard types are summarized here, with emphasis on functional characteristics rather than design details. Major consideration is given to types most widely used in industrial power distribution systems.

## 19. LOW-VOLTAGE SWITCHGEAR

Most industrial power is utilized at voltages ranging from 208 to 600 volts and from substations ranging in size from 100 to 1500 kva. For distributing power at these voltages, the standard type of switchgear is the drawout air circuit-breaker equipment. Figure 45, p. 16-54, shows a typical installation of this type of gear.

The circuit-interrupting devices of this type of gear are air circuit-breakers, produced in several sizes, depending on the continuous current-carrying capacity and the interrupting capacity required. Table 31 shows rating combinations standardized by NEMA for

600-volt a-c air circuit-breakers of the type used in standard drawout metal-enclosed switchgear.

**COMPLETE SWITCHGEAR ASSEMBLIES** embodying the desired arrangements and number of circuits and circuit-breakers of suitable ratings are factory built by manufacturers from standardized subassemblies, so that the user provides only suitable foundations, and connects his cables to the proper terminals to complete the installation. These factory assemblies consist of tiers of standard compartments, each of which contains a circuit-breaker or an instrument and control panel. The circuit-breakers are built on removable carriages, and means are provided to draw the entire breaker out of its compartment for inspection, maintenance, replacement, or for isolation of the circuit. Interlocks are provided to prevent withdrawal or insertion unless the breaker is in the open position. Behind the tiers of breakers and instrument and control compartments is a structure carrying bus bars, connection bars, terminals, and necessary current and potential transformers. The entire structure is housed in a metal enclosure to insure maximum safety to operators and protection to equipment.

From complete listings of standard compartments provided in manufacturers' handbooks and bulletins, suitable combinations can readily be worked out to cover nearly all the usual circuit arrangements encountered in modern low-voltage power generation and distribution. Although space does not permit showing illustrations of all the units of one of

these complete listings, Fig. 46 shows some of the more commonly used standard units. Figure 47 shows a typical assembly of standard units into a complete equipment.

Unit Type	Method of Operation	Maximum Number of Vertical Sections	Ratings of Circuit-breaker in Amperes		Type of Breaker
			Interrupting	Continuous	
A	Electric	1	75,000 and 100,000	2000 to 4000	AL-2-75 and AL-2-100
B	Electric	2	50,000	100 to 1600	AL-2-50
C	Manual	3			
D	Manual or Electric	4	25,000	35 to 600	AK-1-25
D	Manual or Electric	4	15,000	15 to 225	AK-1-15

FIG. 46. Standard metal-enclosed low-voltage a-c switchboards with drawout air circuit-breakers for 600-volt 3-phase 3-wire 60-cycle service. Feeder section units for incoming power line, power transformer, feeder, and motor-branch circuit application.

Standard units are available for the following types of circuit commonly encountered in systems in this voltage range (208 to 600 volts).

- (1) Incoming lines or transformer secondaries up to 4000 amp.
- (2) Generators up to 1650 kva at 240 volts, 3100 kva at 480 volts, or 4150 kva at 600 volts.
- (3) Bus ties up to 4000 amp.
- (4) Feeders up to 4000 amp.
- (5) Synchronous or induction motors, full voltage or line-reactor automatic start up to 500 hp at 230 volts, 1000 hp at 440 volts, or 1250 hp at 550 volts.

Other standard units include the more common combinations of instruments and meters, and provisions for the control of electrically operated circuit-breakers. All circuit-breakers having interrupting ratings of 75,000 and 100,000 amp are electrically operated, and those of lower interrupting ratings are available for either electrical or manual operation. When electrical operation is used, control power transformers are available for control units. Standard auxiliary compartments are available to provide for bus transitions between different-sized units and for accommodation of totalizing metering equipments.

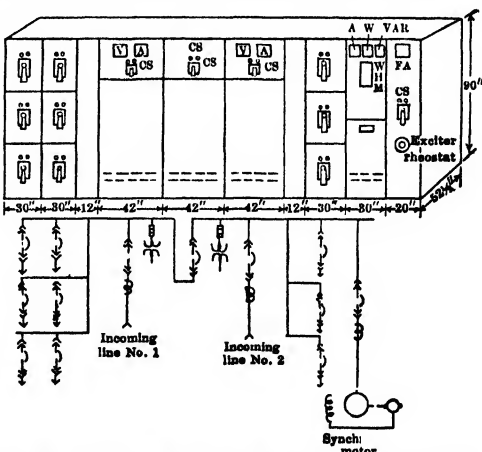

FIG. 47. Typical assembly of standard units into a complete switchgear assembly.

**STANDARD UNIT.** Each standard unit is provided with complete equipment necessary for the circuit. For example, a generator unit includes, in addition to the circuit-breakers, the usual complement of instruments: field switch, exciter rheostat, breaker, governor, and instrument transfer switches, voltage regulator, necessary protective relays, current and potential transformers, and complete main connections, buses, wiring, and terminal facilities. Although usually installed indoors, these equipments are available in weatherproof enclosures for outdoor installation.

One important consideration in the application of low-voltage switchgear is the degree of service continuity required. This determines, in addition to the circuit arrangement, which of two distinct systems of fault tripping in common use is selected. These systems are known as the *selective* and *cascade* systems.

## 20. MEDIUM-VOLTAGE SWITCHGEAR

Power is distributed to load centers at voltages ranging from 2300 to 13,800 volts by medium-voltage switchgear. The type of equipment now almost universally used in this class is known as *metal-clad switchgear*, which has been quite thoroughly standardized. Complete lines of standard circuit units are offered by all leading manufacturers. The circuit-interrupting device used in this type of gear is the power circuit-breaker. The most common form of power circuit-breaker in this voltage class is the magnetic air breaker, although its predecessor, the oil circuit-breaker, is still used to a limited extent, particularly where explosive atmosphere is prevalent as in oil refineries. Power circuit-breakers are produced in ratings shown in Table 32, and complete switchgear equipments are available

Table 32. Metal-clad Switchgear (Oilless)

\* Data from ASA Standard Schedule of Preferred Ratings for Power Circuit Breakers C37.6-1949.

† Voltage ratings based on recommendations of EEl-NEMA Joint Committee on Preferred Voltage Ratings for A-C Systems and Equipment.

‡ 1.5 × 40 ms positive or negative. All impulse values are phase-to-phase, phase-to-ground, and across open contacts.

§ For definitions of short-time current ratings see ASA Standard for A-C Power Circuit Breakers C37.4-1945 or any subsequent edition approved by ASA.

in corresponding ratings. Figure 44, p. 16-51, shows a side view of a metal-clad switchgear unit with the more important components identified. Manufacturers provide complete listings of standard circuit units of this type of switchgear, with three different relative arrangements of the primary circuit equipment with respect to the secondary or control equipment. Selection of the arrangement is usually governed by the layout of the station.

Manufacturers' listings include standard units for the following types of circuits in commonly used ratings: (1) Generators. (2) Incoming lines or power transformer secondaries. (3) Synchronous or induction motors, full voltage, line-reactor, neutral-reactor, or autotransformer automatic start. (4) Feeders. (5) Bus sectionalizing. (6) Generator-neutral grounding. (7) Totalizing metering.

In addition, drawout potential-transformer compartments, bus-entrance compartments, and instrument brackets are available as standard components of complete equipments. For larger size breakers, and where quick removal of breaker units is required, electrically driven elevating mechanisms are available.

## 21. STATION-TYPE AND HIGH-VOLTAGE SWITCHGEAR

**STATION TYPE SWITCHGEAR.** Power usually is generated in large central generating stations at voltages ranging from 13.8 to 34.5 kv. The concentration of power is such as to require switchgear equipment having short-circuit interrupting ratings over the 500,000 kva maximum for which metal-clad switchgear with removable breakers is designed. For this type of service, station-type cubicle switchgear is generally used. The air-blast circuit-breaker is commonly used in this type of gear. This equipment is available in ratings ranging from 14.4 to 34.5 kv, 1200 to 5000 amp continuous, and 500,000 to 2,500,000 kva interrupting rating.

Station-type equipments embody stationary-type oil or air-blast breakers, safety-locked disconnecting switches, bushing current transformers, drawout potential transformers, and segregated phase construction. Control and secondary equipment are not built integral with the primary gear, but as a separately mounted duplex or bench-type switchboard.

The air-blast circuit-breaker interrupts the circuit by means of a blast of compressed air released across the contacts just as the mechanism opens them. The arc drawn between the contacts is rapidly cooled by the expanding air, and interruption occurs very quickly.

Station-type equipments have been standardized to a considerable extent. However, because of the magnitude and importance of installations of this type, manufacturers should be consulted for each application.

**HIGH-VOLTAGE SWITCHGEAR.** The transmission of power in large amounts over considerable distances involves voltages ranging from 34.5 to 287 kv.

Switchgear for such systems up to 69 kv is known in the industry as *package substations*, a more detailed discussion of which was given in Articles 17 and 18. The components of this type of equipment have been considerably standardized, and manufacturers supply coordinated complements to make up complete substations to fit many varieties of circuit arrangement.

The design and application of switchgear to circuits of voltages above 69 kv are usually the joint concern of manufacturers and large utility organizations. The more important components of high-voltage switchgear equipments are: (1) Outdoor power circuit breakers in ratings from 15 to 287 kv, and 50,000 to 10,000,000 kva interrupting rating. (2) Disconnecting switches of many ratings and arrangements. (3) Power fuses. (4) Lightning arresters. (5) Bus supports and insulators. (6) Connectors and fittings. (7) Supporting frame members.

**CONTROL AND PROTECTIVE RELAYING SWITCHGEAR.** In the low- and medium-voltage fields, standard factory-assembled switchgear usually embodies all necessary control and protective relaying functions. However, where station-type and high-voltage outdoor switchgear are used, it is usually impractical to include control and protective relaying functions as part of the main switchgear. For such applications separate switchboards are usually provided upon which control switches, instruments, meters, voltage regulators, and protective relays are mounted. Control and relaying switchboards are manufactured as completely factory-assembled equipments. Manufacturers have standardized structural components from which such switchboards are built. Upon these structures standard groups of control and protective devices for various types of circuit can be arranged to provide convenient and efficient centralized control of the circuits in large stations.

The most common type of switchboard in current use is the duplex board, like that shown in Fig. 48. It consists of front and rear panels separated by a passageway entered through doors at the ends. Control switches and instruments are mounted on the front

FIG. 48. Duplex switchboard.

(See the very complete list of literature on this subject contained in *Bibliography of Relay Literature*, AIEE, Nov. 1947.)

panels, and relays and meters on the rear panels. All devices are dead-front to give maximum safety to operators. Complete wiring and terminal facilities are provided inside the structure.

The most important component of a control and protective relaying switchboard is the very important protective relay. It is the "eyes" of the power circuit-breakers in that it detects the presence and location of abnormal system conditions, such as short circuits or low voltage, and directs the tripping of the correct breakers to remove the faulty part of the system from service quickly and accurately. Standard combinations of relays are available to protect all components of the power system.

## TRANSFORMERS \*

### 22. TRANSFORMER CHARACTERISTICS

**CONSTRUCTION.** A transformer consists of two insulated coils of wire linked with a ring of iron. The coils are called *high-voltage* and *low-voltage windings*, or *primary* and *secondary windings*. The primary winding is connected to the *source of energy*, and the secondary is connected to the *load*. The high-voltage winding is designed for the higher voltage, and has the greater number of turns. The designations *high voltage* and *low voltage* are preferable to *primary* and *secondary*. The ring of iron is called the *core*.

Each coil consists of a number of loops of round or rectangular wire. Several strands may be used in parallel but electrically insulated from each other, from the core, and from the other coil.

The core consists of thin sheets of high-grade silicon steel. The thickness depends somewhat on the frequency at which the transformer is to operate. The thickness commonly used for 60 cycles is approximately 0.014 in.

The primary function of a transformer is to transform electrical energy from one alternating voltage to another. To transform large amounts of energy with maximum efficiency, many factors must be considered in determining the materials, design, and arrangement of the primary and secondary coils and the core.

**RATING** of a transformer or other induction apparatus consists of the output, together with other characteristics, such as voltage, current, frequency, and power factor assigned to it by the manufacturer. It is regarded as a test rating that defines an output which can be taken from the apparatus under prescribed conditions of test and within the limitations of established standards.

The established standard that applies to transformers is American Standards Association C-57. It represents standardized practices in the United States relating to transformers and other induction apparatus. Data in this standard were gathered principally from the established Standards of AIEE and NEMA. It contains information pertaining to definitions of terms, conditions on which the rating and behavior are based, conditions on which acceptance tests are made, and guides for testing and service operation of transformers and other induction apparatus.

**TURN RATIO** is the ratio of the number of turns in the high-voltage winding to the number in the low-voltage winding. At no load the voltage ratio is equal to the turn ratio, but under load the voltage ratio differs from the turn ratio because of the effect of regula-

\* Contributed by E. V. DeBlieux.

tion. (Refer to Standards C-57 for methods for calculating regulation, voltage under load, and other characteristics.)

**NO-LOAD LOSS AND EXCITING CURRENT.** The no-load loss is the energy consumed in a transformer that is excited at rated voltage and frequency but which is not supplying load. The current that flows in the primary winding under this condition is the *exciting current*. The no-load loss varies from approximately 1% of rated output for small distribution transformers to approximately 0.3% for small power transformers, and to approximately 0.25% for very large power transformers. The no-load loss is somewhat less than these figures for low voltage and somewhat higher for high voltage, or three-phase transformers. Practically all no-load loss is in the core. It includes a small dielectric loss in the insulation and copper loss in the windings. For many years core steel used in transformers was hot-rolled into sheets and cut to the dimensions for assembly. Before assembly individual sheets are coated with enamel or other insulation to prevent circulation of eddy currents between the sheets. In recent years a new type of core steel, fabricated by cold rolling, has been developed. This steel has a high percentage of the grains oriented in the direction of rolling; this causes a large reduction in no-load loss and exciting current when the electrical flux is parallel to the direction of the grain. Core designs for power and distribution transformers that make use of this property have been developed.

**LOAD LOSS AND IMPEDANCE VOLTAGE.** *Load loss* is the energy loss incident to carrying load. It includes the losses produced in windings and other metallic parts as a result of the load currents flowing through windings. The voltage required to circulate rated current through one winding while another is short-circuited is the *impedance voltage* for the connection at which the test is made. It is usually expressed as a percentage of the rated winding voltage. It is the resultant of two components, one in phase with the load current, due to winding *resistance*, the other 90 degrees out of phase, due to winding *reactance*. Generally, resistance is small compared with reactance.

**TOTAL LOSS** is the sum of no-load and load loss. It is the loss that occurs during operation at rated voltage and load. Total loss varies from approximately 3% of the rated output for small distribution transformers, to approximately 1% for small power transformers, and to approximately 0.5% for very large power transformers. The total loss is somewhat less than these figures for low voltage and somewhat higher for high voltage or three-phase transformers.

Total loss is a measure of efficiency in transforming power. The figures given above indicate that the full load efficiency of transformers varies from 97% in small distribution transformers to 99% in small power transformers, and to 99.5% in very large power transformers.

**POLARITY OF TRANSFORMERS** refers to voltage vector relations of transformer leads brought outside the tank. Polarity is the relative direction of induced voltage from

FIG. 49. Polarity of transformers.

$H_1$  to  $H_2$  as compared with that from  $X_1$  to  $X_2$ , both being in the same order with respect to the tank. As indicated in Fig. 49, polarity can be additive or subtractive.

ASA Standard C-57 requires that transformer lead designations indicate polarity. When leads are so marked, polarity of transformers is subtractive when  $H_1$  and  $X_1$  are adjacent, and additive when  $H_1$  is diagonally opposite  $X_1$ .

**Test for Polarity—Single-phase Transformers** (see Fig. 50). Connect one high-voltage lead ( $B$ ) to the opposite low-voltage lead ( $C$ ). Apply voltage at  $AB$ . Measure voltage  $V$  between  $A$  and  $B$ , and  $V_1$  between  $A$  and  $D$ . If  $V_1$  is greater than  $V$ , polarity is additive; if less, it is subtractive.

FIG. 50. Connections for polarity test.

**Test for Polarity—Three-phase Transformers.** Each phase is tested in the same manner as indicated for single-phase transformers. All phases should have the same polarity.

**TYPES OF TRANSFORMER.** **Core and Shell Type.** In the *core type* the windings surround and enclose most of the core. In the *shell type* the arrangement is reversed, and the core extends through and loops around the outside of the coils, thus largely surrounding

them. Experience has shown that transformers of either type can be built with equal facility for most applications.

**Dry Type and Liquid Insulated.** In *dry-type transformers* air is the principal electrical insulation between the winding and the core and casing and is also the medium for removing the heat generated in the core and windings.

In *liquid-immersed transformers* these functions are performed by a liquid that may be either transformer oil or the noninflammable synthetic liquid Askarel.

Below is a comparison of the characteristics of transformer oil and Askarel:

	Askarel	Transformer Oil
Color	Straw yellow	Clear
Burning point	None	148 C
Viscosity at 37.8 C Saybolt	40 sec	57 sec.
Pour point	-32 C	-40 C
Specific gravity	1.55	.85

Air- or Askarel-insulated transformers are used in locations where the fire hazard of oil is objectionable. The advantages of Askarel transformers are that (1) they can be installed indoors without the expense of fireproof vaults; (2) in case of failure the products of decomposition of the insulating liquid are noninflammable and nonexplosive; and (3) they can be built for much higher voltage and capacities than air-insulated transformers.

**Self- and Forced-cooled.** Transformers are classified as *self-cooled* or *forced-cooled*, according to the means for dissipating the heat. In dry-type transformers the heat is transferred directly from the core and coils to the air. In liquid-immersed transformers the heat is first transferred from the core and coils to the insulating liquid and then to the radiating surface. A transformer is self-cooled if the heat is transferred directly from the core and coils or from the radiating surfaces by natural circulation of the air. A transformer is forced-cooled if the heat is transferred from the radiating surface by forced circulation of air, usually produced by fans. A transformer is water-cooled if the heat is transferred by forced circulation of water through a water cooler. To improve the transfer of heat from core and coils, the insulating liquid is sometimes forced-circulated between core and coils and the radiating surfaces by an oil pump.

Self-cooling is simplest and most reliable. If a transformer is required to carry overloads a combination of self and forced air cooling is preferable.

The comparative cost per kva for the different types of cooling given in Table 33 shows that high-capacity forced-cooled transformers are lower in first cost than self-cooled ones. Also, Table 33 shows that an oil-to-water cooling system is somewhat lower in first cost than an oil-to-air system except for self-cooled units below approximately 5000 kva. However, many other factors besides first cost must be considered when determining the most advantageous type of cooling for a specific service.

**Table 33. Approximate Price of Standard Power Transformers, dollars per kva \***

SINGLE-PHASE, 60-CYCLE, OIL-INSULATED

\* Price additions are made for special features.

**DISTRIBUTION AND POWER TRANSFORMERS.** Distribution transformers are transformers that have a kva rating of 500 or less, used to distribute power to points of usage. Standard ratings of distribution transformers are given in Table 34. Approximate prices in dollars per kva for representative ratings of distribution transformers are given in Table 35. Price per kva increases with the voltage, and decreases as the transformer kva increases.

Table 34. Standard Distribution Transformer Ratings

Preferred Kva Ratings	Primary Voltage	Secondary Voltage	Kva Range
3			
5	480		
10	600	120/240	3-100
15	4160		
25	2400		
37.5	4800	120/240	
50	7200	240/120	3-167
75	12000	240/480	
100	13200	600	
167	14400		
250	13200 Gr. Y/7200		
333	13200 Gr. Y/7200	120/240	3-100
500	13200 Gr. Y/7200		

Voltagcs up to 110,000 volts are standard in distribution sizes. With 480 or 600 volt primary, two 5% tap voltages below the rated primary voltage are standard. Certain tap arrangements such as two 2 1/2% taps above and two 2 1/2% taps below or four taps below rated voltage are standard for various voltage and kva ratings. Preferred kva ratings of three-phase distribution transformers are 9, 15, 30, 45, 75, 112 1/2, 150, 225, 300, and 500 kva.

Table 35. Approximate Price of Distribution Transformers, Single-phase, 60-cycle, Self-cooled, Oil-insulated

Rating, kva	Primary Voltage			
	2400/4160Y	7200/12470Y	12,000	14,400
3	19.5	23.5	28.5	32.5
5	18.0	22.0	23.5	26.0
10	14.0	17.5	18.0	19.5
15	12.0	15.0	15.0	15.0
25	10.0	12.0	12.0	13.0
37.5	8.5	10.5	10.5	11.0
50	8.0	9.5	9.5	10.0
75	7.0	8.5	8.5	8.5
100	6.5	7.5	7.5	7.5
167	6.0	6.0	6.0	6.0
250	6.0	6.0	6.0	6.0
333	5.5	5.0	5.0	5.0
500	5.0	4.5	4.5	4.5

For 3 to 100 kva the standard secondary voltages are 120/240, 240/480, or 600 volts.

For 167 to 500 kva the standard secondary voltages are 240/480, or 600 volts.

All prices include standard taps.

**Power transformers** are transformers with a kva rating greater than 500. They are located at power-generating stations, at the terminals of power-transmission systems, at the voltage transformation points of the system, and at points of large power usage. Standard ratings of power transformers are given in Table 36. Approximate prices in dollars per kva of representative ratings of power transformers are given in Table 33. Price per kva increases with the voltage; decreases as the transformer kva increases. For the higher ratings the cost decreases with type of cooling in this order: self-cooled, water-cooled, forced-oil-cooled. For the lower kva ratings the order is reversed. Price additions are made for special electrical or mechanical features such as overload capacity, special accessories, extra voltage ratings, low noise level, and noninflammable insulating liquid.

Table 36. Standard Power Transformer Ratings

Voltage Ratings		Preferred Kva Ratings	
Nominal System Voltage	Preferred Voltage Rating	Single Phase	Three Phase
23,000	22,900	667	
34,500	34,400	833	750
46,000	43,800	1,000	1,000
69,000	67,000	1,250	1,200
115,000	110,000	1,667	1,500
138,000	132,000	2,000	2,000
161,000	154,000	2,500	2,500
230,000	220,000	3,333	3,000
		4,000	3,750
For voltages below 23,000 the preferred voltages are the distribution standard voltages		5,000 *	5,000 *
		6,667 *	6,000 *
		8,333 *	7,500 *
		10,000 *	10,000 *

\* Higher standard ratings are multiples of these values.

Some manufacturers have standardized the design and manufacture of the lower voltage and kva ratings which they will supply on quicker delivery and at a lower price.

## 23. TRANSFORMER CONNECTIONS

Connections for three-phase voltage transformations most commonly used are illustrated in Fig. 51.

FIG. 51. Transformer connections.

The advantages and disadvantages of these connections are described below.

**DELTA-DELTA. Advantages.** Most economical connection for large output at low voltage; a 3-phase bank of three single-phase transformers can operate in open-delta at 58% output if one unit fails; third harmonic voltages are eliminated; easy to phase in for parallel operations; heavily unbalanced 3-wire loads can be supplied without serious voltage unbalance.

**Disadvantages.** Copper cross section of both primary and secondary windings is a minimum whereas number of turns and insulation per phase is a maximum; neutral point of windings not available hence neutral of low-voltage winding cannot be grounded.

**STAR-STAR.** Used mainly for three-phase, core-type transformers for small power loads.

**Advantages.** Copper cross section is maximum, number of turns per phase is minimum; most economical for small output at high voltages; both neutrals available for grounding or for balanced 4-wire supply; easy to phase in for parallel operations; can be operated single-phase at 58% output.

**Disadvantages.** Neutral points are inherently unstable unless solidly grounded; unbalanced 4-wire load cannot be supplied unless primary and supply neutral points are tied together for shell-type or banks of single-phase transformers; a fault on one phase renders a 3-phase bank or unit inoperative for 3-phase output; third harmonic voltages exist but can be eliminated if transformer has a tertiary winding, connected delta, which supplies a circuit for third harmonic currents. This delta winding can also supply external loads, and if connected to a synchronous motor or condenser, improves power factor.

**DELTA-STAR.** Used for stepdown transformers to supply 4-wire distribution to motor and lighting loads, balanced or unbalanced; also used for stepping up voltage for power transmission.

**Advantages.** No third harmonic; secondary neutral available for grounding or for 3-phase, 4-wire supply; suitable for unbalanced 4-wire load, resulting unbalanced voltage being relatively small; balanced and unbalanced loads may be applied simultaneously. Transformers of widely different impedances can be used to form a 3-phase bank.

**Disadvantages.** No primary neutral available for grounding; a fault in one phase makes 3-phase unit or bank inoperative.

**STAR-DELTA** connection is used chiefly for stepping down voltages from high-voltage transmission lines.

**Advantages.** Third harmonic voltages eliminated by delta-connected secondary; primary can be grounded; most desirable for stepdown transformers for high-voltage transmission; secondary delta connection stabilizes the primary neutral. Transformers of widely different impedances can be used to form a 3-phase bank.

**Disadvantages.** No secondary neutral available for grounding or for 3-phase, 4-wire supply; a fault on one phase renders a 3-phase unit or bank inoperative.

**OPEN-DELTA.** **Advantages.** A 3-phase, shell-type transformer can operate in open-delta with one damaged phase; two units of a transformer bank consisting of three single-phase units can be operated in an open-delta, since a damaged single-phase unit can be removed entirely.

**Disadvantages.** With delta-connected, 3-phase, shell-type transformers, a damaged phase must be disconnected and short-circuited on itself to prevent voltage being induced by the good phases. To operate a 3-phase, core-type transformer in open-delta, the damaged phase must remain open-circuited and yet be capable of withstanding normal voltage induced in it from the other phase windings. When connected open-delta, current in each transformer is 30 degrees out of phase with voltage, and transformer operates at 86.6% power factor if load is noninductive. Capacity of a 3-phase transformer, or of a 3-phase bank, connected open-delta, with the damaged phase cut out, is 58% of the bank rating. Unbalance in voltages may cause burnout of three-phase motors.

**CONNECTIONS FOR PHASE TRANSFORMATION. Two- or Three-phase to Single-phase.** It is practically impossible to transform from polyphase to single-phase and obtain balanced conditions. The best method is simply to connect the transformer across one phase of a polyphase system. If resulting unbalance is serious, a polyphase motor, driving a single-phase generator, should be used.

**Three-phase to Two-phase.** The most common connection is the Scott connection (Fig. 52), using two transformers, called *main* and *teaser*, T-connected on the 3-phase side. The teaser has 86.6% of the number of turns in the main winding. For supplying 2-phase, 4-wire system on the 2-phase side, both windings are identical and independent.

Usually main and teaser transformers are identical. The 3-phase winding of each has a 50% and 86.6% tap. When used as a teaser, one 3-phase line is connected to the 86.6% tap, and 13.4% of the winding is idle. The Scott connection thus requires 6.7% more copper than single-phase transformers delivering the same power.

**PARALLEL OPERATION OF TRANSFORMERS.** Two transformers having the same ratio, and proper impedance, can be connected in parallel if phase rotation and angu-

Fig. 53. Lead markings and vector diagrams for three-phase transformers.

lar displacement are the same. Delta-delta and star-star transformers have the same angular displacement, when polarity and phase rotation are the same. With delta-star or star-delta transformers, correct adjustment can be made by proper sequence of leads. If voltage diagrams are available, for the transformers to be paralleled it is necessary only that these diagrams coincide and that corresponding terminals be connected together. The basic requirement for parallel operation is that the leads to be connected are at the same potential. When transformer leads are marked in accordance with the ASA C-57 Standard markings, it is necessary only to connect similarly lettered leads together.

Three-phase transformers can be grouped according to their angular displacements. (See Fig. 53.) To operate in parallel, transformers must belong to the same group. One group cannot be changed to another by interchange of external leads. For instance, two delta-delta transformers, one of group 1 and the other of group 2, cannot be operated in parallel. Table 37 shows operative and inoperative connections.

**Table 37. Transformer Operative and Inoperative Parallel Connections**

Operative Parallel Connections				Inoperative Parallel Connections			
Low-voltage Side		High-voltage Side		Low-voltage Side		High-voltage Side	
Bank A	Bank B	Bank A	Bank B	Bank A	Bank B	Bank A	Bank B
Delta	Delta	Delta	Delta	Delta	Delta	Delta	Star
Star	Star	Star	Star	Delta	Delta	Star	Delta

Delta	Delta	Star	Star	.....	.....	.....	.....
Delta	Star	Star	Delta	.....	.....	.....	.....
Star	Star	Delta	Delta	.....	.....	.....	.....
Star	Delta	Delta	Star	.....	.....	.....	.....

**Effect of Ratio on Parallel Operation.** Circulating currents flow in the winding of parallel-connected transformers with unequal ratios of high and low voltage windings. The circulating current is equal to the difference of the two secondary voltages,  $e_1$  and  $e_2$  divided by the sum of the impedances  $Z_1$  and  $Z_2$ , of the two transformers. That is

$$I_c = \frac{e_1 - e_2}{Z_1 + Z_2}$$

All values must be in like units, either ohms or percentages.

**EXAMPLE.** Assume a voltage difference of 2% and an impedance of 4%, in each transformer. Percentage of circulating current  $I_c$  will then be

$$I_c = \frac{2 \times 100}{4 + 4} = 25\%$$

The circulating current is 25% of normal in both windings of the transformers. It adds to the load current in the transformer having the higher voltage and subtracts from the load current in the other.

**AUTOTRANSFORMERS.** When the high-voltage and low-voltage circuits of a transformer have parts of the winding in common, the transformer is called an *autotransformer*. With this arrangement the full winding is normally connected to the high-voltage circuit, and a tap lead is connected to the low-voltage circuits. The autotransformer differs from the conventional transformer in several important respects.

Only a part of the kva transferred from primary to secondary is transformed by the autotransformer. Generally, the percentage of the kva transformed is the same as the percentage voltage transformation, based on the high voltage; that is, if the autotransformer raises the voltage 10% it actually transforms only 10% of the kva transferred to the secondary, hence the autotransformer physical rating need be only 10% of a conventional transformer that transforms 100% of the kva. For these reasons an autotransformer has lower cost, greater efficiency, better regulation, smaller size, and less exciting current than a conventional transformer for the same application. The advantage is greater the smaller the difference between the high and low voltages. Difference in voltage of more than approximately two or three to one is undesirable in autotransformers for reasons of economy and voltage hazards.

A disadvantage of the autotransformer is that high- and low-voltage circuits are connected to a common transformer winding. The result is lower reactance and higher short-circuit currents and forces. Another disadvantage is that, owing to the metallic connection

between the high- and low-voltage circuits, electric disturbances originating in one system affect the other. In particular grounds (especially of the high-voltage circuit), harmonic currents and line transients may produce dangerous overvoltages. For these reasons the high-voltage wye, low-voltage wye, with both neutrals grounded, and with a tertiary winding on the same core, is the preferred autotransformer connection.

**INSTRUMENT TRANSFORMERS** are especially designed to obtain high accuracy of ratio of primary and secondary current or voltage. Those designed for high accuracy of voltage ratio are *potential transformers*. Those designed for high accuracy of current ratio are *current transformers*. Instrument transformers are interposed between high-voltage power circuits and low-voltage instrument, meter, and relay circuits. They enable the meter and relay circuits to indicate accurately the conditions in the high-voltage power circuit.

Instrument transformers are classified in accordance with their ratio and phase-angle accuracy with specified meter and relay burden on the secondary. For details of these specifications, see ASA Standards C-57.

For approximately 15-kv application and below, instrument transformers usually have air or compound for the major electrical insulation. For higher voltages oil or Askarel liquid insulation is used. They are available for both indoor and outdoor service.

## WIRE AND CABLE \*

**Insulated cables** consist of three parts—*conductor*, *insulation*, and *protective finish*. The combinations that can be made from various materials are practically innumerable. This chapter deals with the more commonly used types of cable and their application. Special designs, however, can be manufactured to fit almost any special condition.

Although oil-impregnated, paper-insulated, lead-covered cable is the most economical type for high-voltage underground transmission and distribution, it will not be discussed in detail. It is used primarily by larger utility companies who have specially trained workmen required for its proper installation. The following discussion applies to industrial plants, railroads, and smaller utilities.

Rubber insulation, as a term, applies to compounds made from natural or synthetic rubber. No further distinction is made between these two types, because economic conditions at the time or future technological development could dictate which would be the more logical choice.

## 24. OVERHEAD DISTRIBUTION—OUTDOORS

**OPEN-TYPE CONSTRUCTION** using bare or weatherproof wire is usually the least expensive and is widely used. The wires are mounted on insulators supported on poles or attached to buildings.

The development of rubber-like jackets that provide extremely long life when exposed to outdoor conditions, and increased stress on continuity of service have contributed to a growing use of insulated aerial cable. Normally these cables are supported by a *messenger*, bound to it by the cable manufacturer with metal binding tape, as shown in Fig. 54, or supported in messenger rings. The insulation is usually a rubber compound, but may be varnished cambric. Rubber-insulated cables normally have a synthetic sheath, and at the higher voltages a metal shield may also be required to prevent corona discharge. Varnished-cambric insulated cables usually have a synthetic rubber or resin jacket for moisture protection, followed by a metal armor of material such as bronze or galvanized steel, depending on corrosion conditions.

**AERIAL CABLE** offers advantages over the open-wire construction, such as greater safety, better voltage regulation, better appearance, and greater reliability from faults caused by sleet and wind storms. It can be installed in congested locations, and on existing pole lines that would not carry an additional open-wire circuit.

Fig. 54. Preassembled aerial cable supported by a messenger

\* Contributed by R. B. McKinley.

## 25. UNDERGROUND AND GENERAL PLANT WIRING

Development of more versatile rubber insulation and synthetic jackets has greatly simplified the choice of cable construction for underground and general plant wiring when high reliability is desired. Rubber compounds that are both heat and moisture resistant can be supplied for low-voltage use. High-voltage rubber insulations have ozone resist-

Table 38. Types of Cable for Industrial Applications

Circuits	Voltage	Method of Installation	Type of Cable	Illustration
Incoming Lines or Yard Circuits	5001 to 15,000 volts	In conduit or duct	V.C. lead—1/C or 3/C; ozone-resisting rubber, shield, jacket 1/C or 3/C	Fig. 55, A and B Fig. 55, C and D

		Without conduit	V.C. interlocked armor 3/C	Fig. 55J
Branch Circuits Inside Buildings	0 to 600 volts	(Same as 0 to 600 volt feeder circuits)		
Multiple Conductor Control	0 to 600 volts	In conduit or duct, direct burial, or aerial	Synthetic resin insulation and jacket; rubber insulation, jacket	Fig. 55K
Series Lighting Circuits	0 to 5000 volts	In conduit or duct, direct burial	Synthetic resin; ozone-resisting rubber, jacket	Fig. 55, I and F
Miscellaneous Circuits	0 to 600 volts		Machine tools, pickling plants, battery leads, etc.—type T	Fig. 55I
Portable Circuits	0 to 5000 volts		Synthetic jacketed portable cables—1/C, 3/C, multi-cond.	Fig. 55, L, M, and N

Fig. 55. Types of cable for industrial application.

ance in addition to heat- and moisture-resistant properties. Tough, synthetic jackets, in addition to providing mechanical protection against abrasion, provide oil resistance, retard flame travel, and offer lasting protection against moisture, ozone, and sunlight.

**Synthetic resin insulations** that do not require any additional finish are also available. They can be installed in wet or dry locations. These insulations do not oxidize or convey flame, are practically unaffected by sunlight or ozone, and are highly resistant to the usual oils, acids, and alkalis encountered in service.

It was formerly necessary to use lead-sheathed cable in wet locations, braid-finished cable in dry locations, and metallic-armor finish for burial use. Therefore, all runs had to be analyzed in detail, and two or three different types had to be purchased. Carrying stock for emergencies was a complicated matter. The synthetic-jacketed cables mentioned above can be installed for all these types of installations, greatly simplifying purchasing and stocking problems.

**Varnished cambric insulated cable with interlocking armor finish** has proved to be a very economical cable of great reliability. Its chief advantages, besides low installed costs, are high current-carrying capacity, less space occupied, time saved during original layout planning, and high re-use value.

Commonly used types of cable for the various applications encountered in general plant wiring are shown in Table 38. They are listed according to the application. Illustrations are shown in Fig. 55 to describe constructions shown in the table. Besides those shown in the table, the names of other suitable types may be obtained by reference to the latest edition of the National Electrical Code.

## CONVERSION EQUIPMENT \*

Electric power is frequently available in a form not suited for the application, and must be converted to the desired form. Four modes of electric power conversion are considered; a-c to d-c; d-c to a-c; d-c to d-c; a-c to a-c. Of the various forms of conversion, the most important is a-c to d-c.

In most locations the available power supply is a-c, which must be converted to supply electrolytic, traction, and general industrial d-c loads. These loads include both constant-voltage and variable-voltage loads.

D-c to a-c conversion is limited to special applications.

D-c to d-c conversion usually involves a voltage change. Typical applications are battery charging, d-c welding, and establishment of a neutral in three-wire systems.

A-c to a-c power conversion includes changes in voltage, frequency, or number of phases. Voltage changing by transformers is the commonest mode of a-c to a-c conversion. See Articles 22 and 23.

**MEANS FOR CONVERTING POWER.** The more important means currently in use for the various modes of power conversion are listed here.

**A-c to d-c.** Induction motor generators. Synchronous motor generators. Mercury arc rectifiers. Metallic rectifiers. Hot cathode rectifiers. Synchronous converters.

**D-c to a-c.** Motor generators. Inverted rotary converters. Mechanical inverters. Electronic inverters.

**D-c to d-c.** Motor generators.

**A-c to a-c.** *Voltage:* transformers. *Frequency:* constant-frequency ratio synchronous motor generator sets; variable-frequency ratio motor generator sets; induction generators; motor-driven inductor alternators; electronic converters. *Phase:* phase converting transformers; mechanical phase converters.

## 26. A-C TO D-C CONVERSION

**INDUCTION MOTOR GENERATOR SETS.** Induction motor-generator sets for general-purpose use are standardized for 25- and 60-cycle systems. They have a 2-bearing, squirrel cage induction motor with a short shaft extension, connected through a solid coupling to a single-bearing generator. Foundations to prevent deflection of bases are necessary. Sets larger than 125 kw have speed-limiting devices. D-c generators for three-wire service have two collector rings for obtaining the neutral.

**Ratings.** Induction motor generator sets can be built in ratings as high as several thousand kilowatts. Standard kilowatt ratings of 60- and 25-cycle sets are  $\frac{3}{4}$ , 1, 1  $\frac{1}{2}$ , 2,

\* Contributed by A. Schmidt, Jr.

3, 5, 7 1/2, 10, 15, 20, 25, 30, 40, 50, 60, 75, 100, 125, and 150 kw. At higher ratings, the drive is usually a synchronous motor because of its better power factor.

Momentary loads of 150% of rated generator current, in amperes, are permissible with successful commutation as defined by the AIEE. A service factor of 1.15 applies to all except 50-cycle sets. Temperature rise is 40 C, based on a 40 C ambient and continuous operation at rated load.

Efficiencies, dimensions, weights, and power factors of typical standard units are given in Table 39.

**Table 39. Characteristics of General-purpose Induction Motor-generator Sets**

Rating, kw	250 Volts D-c/220, 440, 550 Volts, 60 Cycles A-c					
	Full Load Efficiency	Full Load Power Factor	Net Weight, lb	Overall Dimensions, in.		
				Length	Width	Height
2	.665	.87	317	32 1/16	17 3/32	14 1/16
5	.70	.88	532	41 3/4	19 13/16	17 1/16
10	.74	.88	790	48 9/16	23 5/8	21
25	.783	.885	1460	58 1/16	27 13/16	25 3/4
50	.823	.88	3755	74 1/4	34	34 15/16
100	.847	.91	5880	85 3/4	38 1/2	40 1/4
150	.847	.885	8295	95 3/8	44 1/8	44 3/16

Parallel operation of motor generator sets usually is practicable. For satisfactory operation, adjustments in the field circuits may be necessary after installation.

**SYNCHRONOUS MOTOR GENERATOR SETS.** Synchronous motors are direct-connected to one or two d-c generators, depending on rating. Two unit sets have three bearings, and three unit sets have four bearings. The bases are not self-supporting and require foundations to prevent deflection. The range of sizes is:

No. Units in Set	D-c Voltage	Kw Range
2	125	50- 500
	250	50-2000
	600	200-4000
3	125	400-1000
	250	2000-4000
	600	2000-8000

Motor power factor is 0.8 leading; service factor is 1.15. Permissible load is 125% for 2 hr with a temperature rise of 55 C. Normal temperature rise is 40 C above 40 C ambient temperature. Momentary loads of 150% on units of 150 kw or less and 200% on larger units are permitted. Table 40 shows approximate efficiencies, weights, and dimensions for representative ratings.

**Table 40. Characteristics of General-purpose 0.8 Power Factor Synchronous Motor-generator Sets**

Rating, kw	250 Volts D-c/2300 Volts, 60 Cycles A-c

2000	.896	103,000	210	136	103

## 27. RECTIFIERS

A rectifier is defined as an integral assembly of elementary devices, each consisting of an anode and its cathode, and having the characteristic of conducting current effectively in only one direction. The mechanism for unilateral conduction varies among different types of rectifiers.

**MERCURY ARC RECTIFIERS** use ionized mercury vapor in an evacuated tube to conduct the current between electrodes. At ratings up to 500 kw at 250 volts and 1000 kw at 600 volts, a typical rectifier consists of an assembly of permanently sealed, single-anode, water-cooled tubes. At higher ratings, single-anode tanks, coupled to a continuously operating vacuum pumping system, are used. Before 1940, most rectifiers were constructed as multiple-anode tanks. Manufacture since that time has been confined largely to the single-anode tank assembly because of its greater efficiency and ease of handling.

**Pumped Rectifiers.** Figure 56 shows a cross section of a typical pumped ignitron rectifier tank. A typical assembly includes six or twelve such tanks, vacuum pumps, circulating pump for cooling water, and water-to-water heat exchanger. When cooling water is not readily available, separately mounted water-to-air heat exchangers may be used. The excitation system is mounted separately. It includes an arrangement of capacitors and reactors for applying a power pulse of short duration and large magnitude to the ignitor, each cycle to start a cathode spot and means for adjusting the voltage of the rectifier by varying the time of ignition. A complete rectifier unit includes the rectifier with its auxiliaries and excitation equipment, power transformer, auxiliary transformer, and a-c and d-c switchgear. Figure 57 shows the connection diagram of a typical rectifier unit. A low-voltage high-current transformer is usually provided to bake out the rectifier and remove foreign gases before placing it in service.

**Sealed Rectifiers.** Figure 58 shows a cross section of a typical sealed ignitron rectifier tube. Six such tubes are assembled with the necessary transformer and a-c and d-c switchgear to form a unit d-c substation. Since tap water is frequently used for cooling, and no vacuum pumping system is needed, there is a considerable reduction in auxiliary equipment as compared with pumped rectifiers.

**Ratings.** D-c unit substations employing sealed ignitrons are supplied in ratings as follows:

D-c Volts	Kw
125	40- 200
250	75- 500
600	100-1000

These substations include transformer, auxiliaries, and complete switchgear.

Pumped rectifier units are supplied in the following ratings:

D-c Volts	Kw
250	500-2500
600	750-6000
1500	750-6000
3000	750-6000

Tables 41 and 42 show characteristics of typical pumped rectifiers and d-c unit substations using sealed rectifiers.

**Table 41. Characteristics of General-purpose Pumped Ignitron Rectifiers \***

250 VOLTS D-c											
Rating, kw	Rectifier				Transformer				Efficiency		Loss at No Load, kw
	Wt., lb	Length	Width	Ht.	Wt., lb	Length	Width	Ht.	Full Load	1/4 Load	
750	5900	96	59	78	7,200	132	90	122	.907	.902	7.7
1000	5900	96	59	78	9,000	132	95	122	.904	.906	8.7

\* Dimensions are in inches.

(Continued on p. 16-81)

FIG. 56. Mercury arc rectifier, pumped ignitron type, 3000 kw 625 volts.

**Table 42.** Characteristics of Typical 250-Volt D-c Unit Substations with Sealed Ignitron Rectifiers, Transformers, and A-c and D-c Switchgear

Rating, kw	Wt., lb	Dimensions, in.			Efficiency		Loss at No Load, kw
		Length	Width	Height	Full Load	1/4 Load	
100	12,000	204	75	90	.902	.862	2.5
300	18,500	222	75	90	.909	.902	4.1
500	30,500	276	75	112	.912	.907	5.0

**Overload Rating.** Rectifiers are generally given the same short-time and long-time overload ratings as corresponding motor generator sets. An important advantage of mercury arc rectifiers is that they are capable of withstanding very high momentary overloads without damage.

**Losses.** The principal losses in a rectifier are: (1) *Arc loss*, which is a d-c voltage drop in the mercury vapor, with a nearly constant value of 16 to 20 volts. (2) *Transformer losses*, which vary from 1 to 2½% of the rectifier rating. (3) *Auxiliary losses*, which vary from 1½ to 6 kw, depending on the type of rectifier.

Figures 59 and 60 show the total losses of various forms of conversion equipment over the load range for two typical equipment ratings. The low losses of rectifiers at light loads are noteworthy and account for their early acceptance in the traction field.

Since the arc drop is nearly constant, the efficiency of the rectifier increases with output voltage. Figure 61 shows the efficiency of rectifiers and motor generators as a function of d-c output voltage.

**Fig. 58.** Mercury arc rectifier, sealed ignitron type, 300 kw, 250 volts.**Fig. 59.** Comparative losses in 300-kw 275-volt conversion equipment. Curve A is for synchronous motor generators. Curve B is for mercury-arc rectifiers.

Figure 62 shows the relative efficiencies of rectifiers, rotary converters, and motor generators rated 1500 kw, 600 volts.

**Regulation** of an uncontrolled rectifier is similar to that of a shunt generator having a droop of about 6% from light load to full load. The excitation system can be arranged to shift the phase of anode firing to vary the output voltage. The control power for this circuit is regulated by a voltage regulator, and the output voltage can be controlled so as to be constant, or to rise or droop by a predetermined amount with increasing load. Current practice is to provide general-purpose rectifiers with voltage regulators to maintain constant output voltage.

**Parallel Operation.** When unregulated rectifiers are operated in parallel, they share the load in accordance with the droop in their respective regulation curves. If voltage regulators provided with equalizing windings are used, rectifiers may be operated in parallel with each other or with d-c generators, with correct load division over the load range.

**Power Factor.** The rectifier always has a lagging power factor. It takes reactive power in transferring current from one anode to another, and the use of phase control to reduce the d-c voltage increases the reactive power. The harmonic currents taken by the rectifier

FIG. 60. Comparative losses in 7000-kw 800-volt conversion equipment. Curve A is for synchronous motor generators. Curve B is for mercury-arc rectifiers.

from the line reduce the power factor further. The value of power factor at full voltage depends on the transformer reactance. Representative full-load values are 0.93 for six-phase rectifiers and 0.96 for twelve-phase rectifiers.

**Protection.** The mercury arc rectifier is subject to arc-back or loss of valve action. Arc-back may be the result of operation at excessive cooling water temperature, poor vacuum, or sustained overload. It is equivalent to a short circuit of the rectifier transformer. If the rectifier supplies a counter emf load, then arc-back is also equivalent to short circuit of the d-c bus. When the system potential fault current is excessive, high-speed

reverse-current breakers are used to disconnect the rectifier in 0.016 sec or less. Medium-speed switchgear is used to clear faults in smaller systems.

**Uses.** With few exceptions, rectifiers may be employed as power converters wherever a-c to d-c motor generator sets or synchronous converters might be used and are generally preferred because of their better efficiency, quietness, lower maintenance cost, and ease of application. Rectifiers are not well suited to handle regenerative loads without considerable complication, if such loads have a large magnitude or high repetitive rate. Moderate or infrequent application of regeneration, as in the case of hoists or elevators, is handled with a regenerative braking resistor.

The use of rectifiers is widespread in the electrochemical and transportation fields, and is gaining ground in the industrial field, particularly in the mining industry. In addition to industrial use as a constant voltage source, rectifiers are often arranged to control voltage from zero to full voltage, and are then used to supply individual motor drives where speed control over the entire speed range is required.

FIG. 61. Effect of output voltage on efficiency of conversion equipment. A. Rectifier. B. Synchronous motor generator.

100.

FIG. 62. Comparative efficiency of various types of conversion equipment rated 1500 kw, 600 volts. A. Mercury arc rectifier. B. Synchronous converter. C. Synchronous motor generator.

volts and 3 to 15 amp. (2) *General industrial applications* at 125 to 500 volts, such as supply for d-c motors, magnets, etc., at currents up to 40 amp. (3) *High-voltage applications*, principally broadcasting, at voltages up to 20 kv, and currents up to 30 amp.

Hot cathode rectifiers are often built with grids to regulate the output voltage. Such rectifiers may be used for operation of d-c motors up to 15 hp, with speed control over the entire speed range down to zero speed. Control may be made responsive to any one of a number of conditions of the output of the machine driven by the motor, depending on the application, such as tension, thickness, width, register (printing), speed, and weight. As a result, electronically controlled motors find wide use in a number of industrial applications, including paper, textile, rubber, machine tool, steel, printing, glass, and food.

Life expectancy of hot cathode rectifiers varies with the type of tube. It is usually a year or more.

**METALLIC RECTIFIERS** consist of plates of aluminum or copper, coated with selenium oxide or copper oxide, respectively. These combinations have unilateral conductivity.

**Ratings.** A unit rectifier, consisting of 4 plates, may be capable of delivering 0.1 to 4 amp or more at 4 to 16 volts d-c, depending on the size and type of the plate. A rectifier consists of a sufficient number of plates connected in series and parallel to deliver the desired output. The maximum efficiency of a metallic rectifier is approximately 0.80 so that it is competitive with other types of rectifier in smaller ratings. Rectifiers of this type are built with maximum ratings of a few kilowatts at voltages of 6 to 10,000 volts, except that at voltages under 50, ratings may be extended to about 100 kw.

Life of metallic rectifiers appears to be unlimited when they are operated within their rating. During the first few months of operation an aging process occurs, resulting in an increase in voltage drop and a consequent loss of 3 to 5% in efficiency.

The largest market for metallic rectifiers is in the battery charging field. An important application in the power field is for the supply of large currents at low voltages for electroplating and for the tinplating of steel, where currents of hundreds to thousands of amperes are required at 6 to 40 volts.

**SYNCHRONOUS CONVERTERS** comprise a synchronous motor and a d-c generator combined in one machine, with an armature winding common to both a-c and d-c circuits. Such a machine has an advantage over a motor generator set in efficiency, but is subject to the disadvantage that its output voltage varies with the a-c supply voltage and is not readily controlled except by use of transformer taps or an additional booster generator. Although the rotary converter has a higher efficiency than the rectifier at full load, its light load losses are considerably greater, so that the rotary converter is at a disadvantage in the transportation field, as compared to the rectifier. Because of the low light load losses, simplicity of voltage control, and ease of maintenance of the mercury arc rectifier, the use of rotary converters has declined considerably in favor of rectifiers in the last fifteen years.

## 28. D-C TO A-C CONVERSION

**MOTOR GENERATOR SETS.** Most applications requiring conversion from d-c to a-c are handled by motor generator sets. Data applying to synchronous motor d-c generator sets apply to these units, but when operating inverted the output of standard a-c to d-c sets is 80% of the rating of the d-c unit.

The synchronous rotary converter can be operated inverted to supply an a-c load. Machines are built for this service up to 20 kw. Their use is limited because of their poor voltage and frequency regulation, especially with lagging power factor.

**MECHANICAL INVERTERS** employing a vibrating reed are frequently used for conversion of small amounts of power from d-c to a-c, as for automobile radio receivers and railway coach fluorescent lights. Their capacity is limited by the power that can be handled by the vibrating contact that acts as a switch in connection with an oscillating circuit.

**ELECTRONIC INVERTERS** consist of hot-cathode grid-controlled rectifiers or mercury arc rectifiers excited in such a manner that they can convert d-c to a-c. When operated in this manner, they take reactive power from the a-c system so that they can be operated only where the a-c system has an excess of reactive power capacity available. This form of converter is occasionally used on an electric railway to return regenerative power to the a-c system, or as an element of an electronic frequency converter. It is also used as a part of electronic control of small d-c motors to provide regenerative braking.

## 29. A-C TO A-C CONVERSION

**VOLTAGE.** The commonest form of a-c to a-c conversion is voltage changing by transformers (see Art. 22).

**FREQUENCY CONVERTERS.** Interchange of power between two systems having constant, but different, frequencies is effected through a frequency changer consisting of

two synchronous machines having a suitable ratio of number of poles. Power control is effected by rotation of the stator of one machine with respect to the other.

When the frequency ratio is not constant, one of the machines is a wound-rotor induction machine instead of a synchronous machine, and additional rotating equipment is required to control the transfer of power between the two systems.

When 3-phase power is required at a frequency up to a few times the supply frequency, an induction generator is frequently used. This consists of a wound-rotor induction motor, whose stator is excited at the supply frequency and whose rotor is driven by a second induction motor at a speed such that the desired frequency appears at the rotor slip rings. Such units are used for driving high-speed induction motors for wood working, grinders, etc.

Induction heating or melting requiring single-phase power at frequencies of 500 to 10,000 cycles is ordinarily supplied by inductor alternators driven by standard induction motors. For high-frequency heating applications requiring more than 10,000 cycles, electronic frequency changers are used. Such frequency changers use high-vacuum tubes and generating circuits similar to those of radio transmitters.

Frequency conversion at power frequencies may be carried out electronically by means of a rectifier and an inverter. This scheme requires no definite frequency ratio. Units have been constructed in capacities up to 20,000 kw.

**PHASE CONVERSION.** Polyphase phase conversion, as 3 to 2 phase, is accomplished with transformers with suitable winding ratios and taps (see Art. 23).

Phase conversion from polyphase to single phase, required to avoid unbalance due to excessive single-phase loads, as in a-c traction, is accomplished with a motor generator.

## POWER-SUPPLY ECONOMICS \*

### 30. ELECTRIC POWER DEVELOPMENT IN THE UNITED STATES

The electric system for the production, transmission, and distribution of electric energy was conceived by Thomas A. Edison and first applied by him to serve the Wall Street district in New York City. The electric power industry, as such, dates from Sept. 4, 1882,

the date of initial service of the Pearl Street Station, the first central station built to generate electric power in bulk. The primary elements of an electric system as conceived by Thomas A. Edison have been retained to this day. Such differences as have since developed reflect technological progress in the art of design and application without change in fundamental concepts.

**GROWTH** of the industry, though slight in the years immediately following its inception, has accelerated since 1920. Electric energy production for public use from all sources, excluding industrial plants, increased from 39.4 billion kilowatt-hours in 1920 to 255.7 billion kilowatt-hours in 1947. This represents a 6.5 fold expansion during the 27-year period.

Fig. 1. Growth of electric utility output by sources of energy.

year period and an average increase of 24% of the 1920 power production each year. Alternatively, it represents a secular trend of 7.2% increase each year.

Plants producing electric energy may be classified as steam-electric, utilizing solid, liquid, and gaseous fuels, hydroelectric, utilizing the available energy from the flow of water, and internal-combustion plants. The steady increase in supply from these sources

\* Contributed by M. J. Steinberg.

is illustrated in Fig. 1, and the relative outputs in Fig. 2. Figure 2 shows that the supply of electric energy from the several sources has been maintained at relatively constant proportions.

Hydroelectric generation has varied between 30.5 and 40% of the total generation, the average for the last five years being about 35%. Hydro sources of electric energy have been increased considerably by federally owned and operated hydro projects.

This increase has been offset by additions of privately owned steam-electric plants, giving a relatively constant ratio. Growth in capacity of hydro and fuel-burning plants is shown in Fig. 3. A breakdown of plant capacity between public and private ownership is shown

Fig. 2. Per cent of total power generation, by sources of energy.

Fig. 3. Installed generating capacity of all-electric power plants contributing to the public supply

in Table 1. Nationwide, 19.8% of the total installed capacity is publicly owned. Public ownership extends to 40.3% of the hydro capacity; 9.3% of the steam capacity; and 67.7% of the internal-combustion capacity.

Table 1. Installed Capacity As of Dec. 31, 1946

(Adapted from Federal Power Commission Report S-49)

Ownership	Hydro		Steam		Internal Combustion		Total	
	Kilowatts	%	Kilowatts	%	Kilowatts	%	Kilowatts	%

Total— kw	14,849,036	100.0	34,304,910	100.0	1,149,714	100.0	50,303,660	100.0
%	29.5		68.2		2.3		100.0	

\* Includes Federal Hydroelectric Projects, Rural Cooperatives, and Municipal Systems.

Geographical distribution of electric energy production is shown in Table 2. Fuel consumption for electric energy production is shown by geographical divisions for the calendar year 1946 in Table 3. Consumption of coal in the Middle Atlantic and East North Central States accounts for 72% of the total coal used; 30% of the total oil was burned in the Pacific States, and 55% of the total gas was used in the West South Central States.

(Continued on p. 16-88)

\* Includes bituminous coal, anthracite and lignite.

FIG. 4. Improvement in steam-electric power-plant thermal efficiency.

Improved thermal efficiency of steam-electric power plants is illustrated in Fig. 4 by the annual heat rates of selected plants, typical of the state of the art as of the year indicated. The steady downward trend of plant heat rate is reflected in Fig. 5, which shows the aver-

Fig. 5. Average coal rate for public supply of electric energy. (Based on total coal and coal equivalent of oil and gas.)

age rate of fuel consumption per kilowatt-hour based on total fuel consumption for public supply of electric energy, including the coal equivalent of oil and gas fuels. A similar trend with respect to the price paid for electric energy (Fig. 6) is in sharp contrast to the rising cost of living and to the rising cost of labor, materials, and supplies for the production of electric energy.

Fig. 6. Price of electricity in relation to the cost of living.

## 31. INVESTMENT

**GENERATING-PLANT INVESTMENTS.** Investment in electric utility plant covers facilities for production, transmission, distribution, and general purposes. Studies of unit investment costs are available in a report by the Federal Power Commission (Publication FPCS-18), derived from data for the year 1938 as submitted by 393 large companies comprising in excess of 95% of the nation's privately owned electric light and power industry. A summary of production plant investments is presented in Table 4 for the

Table 4. Production Plant Investments

three major sources of supply. Relative distribution plant and overall plant investment are shown in Tables 5 and 6, respectively. In general, the unit investment per kilowatt of plant capacity is influenced by (1) plant site, (2) design, and (3) size of plant. For fuel-burning plants, the components of investment are land, structure, and equipment. In addition to these, hydro plants also require investments in reservoirs, dams, and waterways.

Table 5. Ratios of Distribution Plant Investment

Item	Percentage
Land and land rights	1.6
Poles, towers, conductors, etc.	30.5
Underground conductors, etc.	18.6
Transformers, services, and meters	27.1

Transmission	14.7
General	4.8
Intangible *	1.9
Total	100.0

\* Capitalized value of rights, fees, franchise, etc., not subject to classification as physical plant.

**Unit Investment Cost for Steam Stations.** The study for steam-electric generating stations, based on reports for 150 generating stations (representing one-third of the total privately owned steam-electric plant capacity in the country), indicates that the unit investment per kilowatt of capacity decreases as the plant increases in size up to 50,000 kw. The decrease in unit investment is relatively slight and negligible as the size of plant increases above 50,000 kw. Land is a relatively minor item of the total investment. The unit investment in structure is but slightly affected by plant size. Unit investment in equipment, including boilers, prime movers and generators, accessory electric equipment, and miscellaneous power plant equipment, is largely dependent on economies in costs

that are greatly influenced by size and design of the plant. Unit investment in structures is fairly constant for plants in excess of 2,000 kw capacity, and it may therefore be expected that, for a given design, the total cost of station structures will be in practically direct proportion to plant size.

**Unit Investment Cost for Hydro Stations.** The survey for hydroelectric generating stations indicates a higher investment per kilowatt than for steam plants, averaging \$100 and \$181 per kilowatt, respectively, for steam and hydro stations. The corresponding average plant capacities are 60,000 and 10,000 kw, respectively. For equal plant size, the difference in unit investment is reduced. Thus for plants of 100,000 kw capacity, the unit investments per kilowatt become \$100 and \$160, respectively, for steam and hydro installations. Unit investment for hydro stations decreases rapidly with size up to capacities of 50,000 kw, and only slightly for plant capacities in excess of this value. Investment in hydro equipment amounts to about one-half that shown for steam-generating stations. The larger investment in the steam stations is attributed to the investment in boiler plant equipment, which also accounts for the higher investment in structures. More than two-thirds of the total hydro plant investment is in reservoirs, dams, waterways, and land, the cost of which is the principal reason for the relatively higher investment in hydro stations than in steam stations of the same size.

**Unit Investment Cost for Internal-combustion Stations.** The survey of internal-combustion engine generating stations is based on reports for 95 stations ranging in size from 250 to over 5000 kw. Since this type of plant is limited to capacities considerably less than those for steam and hydro, comparisons of unit investment costs on an overall basis are not of much value. For a plant of 10,000 kw, however, comparative unit investments are \$110, \$200, and \$130, respectively for steam, hydro, and internal-combustion engines. In general the unit investment per kilowatt decreases with plant size as for steam and hydro plants. Investment in equipment represents the largest item.

**TRANSMISSION PLANT INVESTMENT.** **Unit Transmission Line Investment.** Transmission plant includes high-voltage *transmission lines* and associated *substations*. Unit investments per structure mile for transmission lines (consisting of poles, towers, and conductors but excluding land, land rights, and clearing of land rights of way) increase *linearly* with transmission voltage, for a specified design. The ranges of investment for four common types are:

- (1) Wood pole single-circuit lines, from approximately \$1600 per mile at 11 kv, to \$3800 per mile at 66 kv.
- (2) Wood H-frame single-circuit lines, from \$4100 per mile at 66 kv, to \$6800 per mile at 132 kv.
- (3) Steel tower single-circuit lines, from \$5900 per mile at 33 kv, to \$10,600 per mile at 132 kv.
- (4) Steel tower double-circuit lines, from \$11,800 per mile at 33 kv, to \$18,000 per mile at 132 kv.

**Transmission substation investment** per kva of capacity, exclusive of land and land rights, tends to decrease but slightly with increase in capacity provided. The range of variation is from slightly in excess of \$11 per kva for capacities under 10,000 kva to approximately \$10 per kva for capacities of 100,000 kva and larger.

**The cost of land**, including land rights for both transmission lines and substations and the cost of clearing line rights-of-way, varies considerably, from a minimum value of 1.5% to a maximum value of 30% of the total transmission plant investment. The overall average for 89 companies as of Dec. 31, 1938, was 11.7%, and as of Dec. 31, 1943, 12.4%.

**DISTRIBUTION PLANT INVESTMENT** includes land and land rights, substations, overhead conductors and supporting structures, underground conduit and conductors, line transformers, services, and meters. In addition, it is the practice to include investment in street lighting and signal system equipment. Investments are affected to a considerable extent by customer density, which may be measured by the number of meters per wire mile or per circuit mile. A circuit mile is assumed to equal three wire miles. Investments per wire mile and per meter are shown in Fig. 7.

**Street lighting and signal system investment** includes equipment used wholly for public street and highway lighting, and traffic, fire alarm, police, and other signal systems. Ownership may vary from full ownership by the utility to varying degree of joint ownership with the community served. Investment is best related to distribution plant investment, which may vary from 3 to 5%, the average derived by the Federal Power Commission as of Dec. 31, 1938, being 3.6% of distribution plant investment.

**GENERAL PLANT INVESTMENT** includes land and structures for office buildings and general purposes, office furniture and equipment, transportation equipment, tools, communication, and other miscellaneous facilities incidental to but not otherwise assign-

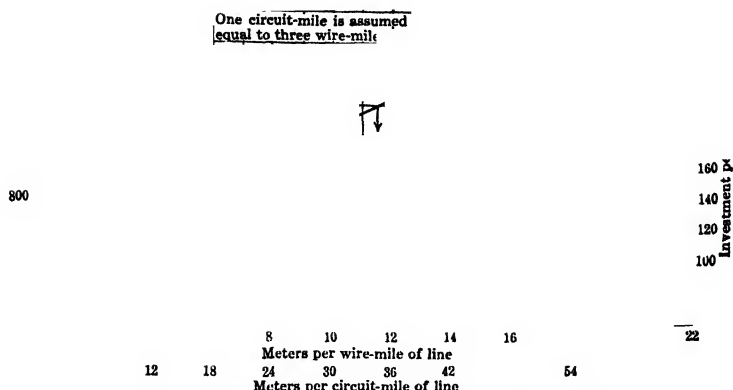

Fig. 7. Distribution-plant investment exclusive of street lighting and signal systems. (Data from the Federal Power Commission)

able to specific operations. General plant investment varies from 4 to 6% of total plant investment, depending on the type of production plant installed. A nationwide ratio of 4.8% was derived by the Federal Power Commission as of the end of the year 1943, as shown in Table 6.

## 32. ANNUAL FIXED CHARGES

Annual fixed charges or annual carrying charges on investment are the charges against revenue for depreciation of physical property, interest charges on capitalization, property, income, and miscellaneous taxes, and the cost of property insurance. The charges are said to be "fixed" because they are essentially a function of the amount of capital investment and practically independent of the quantity of electric energy produced.

The range of fixed charge rates applicable to book cost of investment are:

	Percentage
Depreciation	1 to 5
Taxes	2 to 5
Interest	4 to 8
Insurance	0.05 to 0.3
Total	to 18

**DEPRECIATION** is the reduction in value of property due to its decreased ability or capacity to perform present and future services. Depreciation has been defined as the consumption of investment in property; or the loss in service capacity of property because of use, wear and tear, physical deterioration, the current action of the elements, obsolescence, inadequacy, or the demands of public authority. Briefly, depreciation results from the usual forces and conditions which limit the service life of property and cause its retirement.

**Actual depreciation** is the true or actual decrease in value of property as determined from the physical inspection of the property by competent engineers qualified as valuation experts. Determination of actual depreciation is costly and impractical for properties of extensive magnitude and is therefore seldom resorted to.

**Theoretical depreciation** is the decrease in value of property as determined by the application of some theoretical method, generally by accountants for accounting purposes.

**Depreciation expense** (depreciation charge) is the amount of money that the accountant allows for depreciation as an expense against revenue in his financial statements.

**Depreciable value** is the depreciation of property from its value new. It is equal to the difference between its value when new and its salvage value at retirement.

**Salvage value** of property is the net sum of money realized over and above removal costs, upon retirement at the end of its service life.

**Service life** of property is the period from the date of initial service or installation to the date of retirement.

**DEPRECIATING ACCOUNTING.** The various methods in common use for determination of annual depreciation expense are briefly described below, for which the following notation is used:

$P$  = initial investment, first cost, value new or book cost, dollars.

$L$  = net salvage value of the property at the end of its service life, dollars.

$n$  = estimated service life of the property, years.

$i$  = annual earning rate of invested funds, expressed in percentage but used as a decimal in appropriate formulas.

$D$  = annual depreciation expense, depreciation charge, or annual depreciation, dollars.

$x$  = age of the property, years.

$D_x$  = accrued depreciation to the end of  $x$  years, dollars.

$D_n$  = depreciable value of the property, dollars.

$B_x$  = book value of property as of the end of  $x$  years, dollars.

Then, regardless of the method used to determine the annual depreciation  $D$ ,

$$D_n = P - L \quad (1)$$

$$B_x = P - D_x \quad (2)$$

**Sinking-fund Depreciation.** The annual depreciation  $D$  is that sum which, invested at the end of each year at interest rate  $i$  compounded annually, accumulates to the depreciable value of the property  $D_n$  at the end of its service life  $n$ .

$$D = (P - L) \left[ \frac{i}{(1 + i)^n - 1} \right] \quad (3)$$

$$D_x = (P - L) \left[ \frac{(1 + i)^x - 1}{(1 + i)^n - 1} \right] = (P - L) \left[ \frac{i}{(1 + i)^n - 1} \right] \left[ \frac{(1 + i)^x - 1}{i} \right] \quad (4)$$

**Straight-line Depreciation.** Annual depreciation  $D$  is equal to the total depreciable value  $D_n$  divided by the estimated service life  $n$ .

$$D = \frac{P - L}{n} \quad (5)$$

$$D_x = \frac{x}{n} (P - L) \quad (6)$$

This method assumes that the book value  $B_x$  decreases linearly with age.

**Diminishing Value Depreciation.** Also known as *Reducing Balance Depreciation* or *Fixed Percentage Depreciation*.

Annual depreciation  $D$  is a fixed percentage  $f$  of the book value of the property as of the beginning of the year. The percentage  $f$  remains constant, but the annual depreciation  $D$  decreases with the age of the property  $x$ .

$$f = 1 - \sqrt[n]{\frac{L}{P}} \quad (7)$$

$$D = f(B_{x-1}) \quad (8)$$

$$D_x = P \left[ 1 - \left( \frac{L}{P} \right)^{x/n} \right] \quad (9)$$

$$B_x = P \left( \frac{L}{P} \right)^{x/n} \quad (10)$$

In addition to the foregoing, other methods are employed. Some utilities set aside fixed percentages of the revenue for annual depreciation. Some do not employ any definite method of calculation. Instead, amounts are credited to reserve funds for retire-

**Table 7. Relationship of Depreciation Reserves and Depreciation Expense to Total Electric Plant and Estimated Depreciable Electric Plant—by Depreciation Method**

(Federal Power Commission, 1945)

ments, in each year or from time to time after inspection of the property, which in the judgment of the management will be sufficient to provide for current retirements and to build up reserves against future retirements. A study by the Federal Power Commission for the year 1945 indicates that slightly more than 52% of the companies reporting used the straight-line method of computing annual depreciation charges. For 1937 only 15% of the companies used this method. The study reveals that there is a marked trend toward the general adoption of the straight-line method for providing for depreciation.

Table 7 shows the relationship of depreciation reserves and depreciation expense to total and depreciable plant investment as reported for the year 1945. The ratios to total plant are somewhat lower than the corresponding ratios to depreciable plant, since depreciable plant excludes land investments not generally considered to be depreciable.

A summary of the depreciation rates reported by 38 utilities employing the straight-line method for providing for depreciation for various plant accounts is presented in Table 8.

**INTEREST** is the cost of money use. As an item of the fixed charges on plant investment, interest includes payment of interest on long-term or bonded indebtedness, dividends on outstanding preferred and common stock, and taxes on revenue and income imposed by federal, state, and municipal authorities.

**TAXES**, one of the larger items chargeable against revenue, vary with location. A detailed tax statement from the annual report of the Consolidated Edison Company of New York, Inc., for the year 1947, presented in Table 9, indicates that tax payments amounted to 20.6% of total revenues.

### 33. COST OF PRODUCING POWER

**PRODUCTION EXPENSE. Steam Plants.** The production costs of steam plants vary with many factors which make comparison on a comparable basis difficult if not impossible. The thermal performance is a function primarily of station design as related to size of units, operating steam pressure and temperature, heat balance cycle, and type and method of fuel firing. For a fixed design, the thermal performance depends on such factors as load cycle, load factor, and plant factor. Production costs generally include the costs for fuel, labor, repairs, and supplies, of which fuel may represent 60 to 80% of

the total production cost. Table 10 presents production cost data for selected large steam plants for the year 1946. It is readily seen by inspection of this table that a low production cost is due to either low heat rate (high thermal efficiency) or low fuel price or a combination of both.

**Internal-combustion Engine Plants.** The cost of producing electric energy with internal-combustion engines is influenced by the size and speed of the units, type of fuel injection, and utilization of the heat in the exhaust. Fuel oil, a major item, represents about 30 to 50% of the total cost. A survey by the Federal Power Commission for 1938 to determine the relation of production cost to plant size indicates the following:

Station capacity, kw	0-500	500-2000	Over 2000
Average capacity, kw	243	943	3287
Production expenses, mills/kwhr			
Fuel	7.1	4.9	3.9
Labor and materials	14.1	5.6	4.4
Total	21.2	10.5	8.3

**Hydroelectric Plants.** The items of production expense for hydroelectric generation are labor, maintenance, and supplies. The unit production cost is a function of the installed capacity as illustrated in Fig. 8.

Fig. 8. Production expenses of hydroelectric stations, 1938. (Data from the Federal Power Commission)

**TRANSMISSION AND DISTRIBUTION EXPENSE.** Transmission line operating expenses include operation, supervision and engineering; load dispatching labor and expenses; operation of lines and maintenance of poles, towers, fixtures, and overhead conductors and devices. For a fixed design, the annual operating cost per structure mile of line varies with the operating line voltage. Referred to 1937 and 1938 prices, this expense may be determined as follows.

For single-circuit-H-frame construction:

$$C = 27 + 0.273 (kv)$$

For single-circuit-single-pole construction:

$$C = 24 + 0.767 (kv)$$

For single-circuit-steel-tower construction:

$$C = 50.5 + 0.752 (kv)$$

where  $C$  = operating expense per structure mile in dollars per year, and  $kv$  = line voltage, kilovolts.

Transmission substation operating expenses include operating supervision and engineering, load dispatching labor and expenses, operation of stations and maintenance of structures and station equipment. Referred to 1938 price levels, this expense averages 30 cents per kva of substation capacity.

\* Equivalent coal price, \$/ton. † Included as equivalent coal. ‡ Included with labor cost.

**Distribution expenses** include operation supervision and engineering, load dispatching, distribution office expenses, and operation and maintenance of distribution substations and lines with appurtenant fixtures, conductors and devices, line transformers, services, meters and installations on customers' premises. Although this operating expense is influenced by the design of the distribution system, load density, and size of company, the variation in cost per customer with the number of customers served per pole mile of line is relatively small. The average expense per customer for 213 companies reporting to the Federal Power Commission for the year 1938 was \$6.14. The average for 182 companies serving 100,000 customers or less amounted to \$5.60, and for 31 companies serving more than 100,000 customers, \$6.53.

**Streeth lighting and signal system operating expenses** include the cost of labor and materials incurred in the operation and maintenance of overhead and underground street lighting systems and traffic, fire, police, and other signal systems. This expense averages about 15% of the revenue derived from this class of service.

**MISCELLANEOUS OPERATING EXPENSES.** Accounting and collecting expenses include the cost of labor and materials used in connection with customers' contracts and orders, meter reading, billing, collecting and accounting, and charges for uncollectible accounts and rent expenses.

**Sales promotion expenses** include supervision expenses, salaries and commissions, demonstration, advertising, and other sales expenses and rents.

**Administrative and general expenses** include salaries and expenses of general officers, executives, and other general office employees, general office supplies and expenses, management and supervision fees and expenses, special services, legal services, regulatory commission expenses, insurance, injuries and damages, employees' welfare expenses and pensions, maintenance of general property, rents, franchise requirements, and miscellaneous general expenses.

Cost for the foregoing items range in value as follows:

	Range	Average
Accounting and collecting, per customer	\$2.50-\$ 4.86	\$3.25
Sales promotion, per cent of operating revenue	1.1 - 3.7	2.5
Administrative and general, per cent of operating revenue	5.0 - 10.3	6.3

### 34. LOAD CURVES

**Chronological load curve** is a graphical representation of the variation in demand with respect to clock time. Variation in demand may be due to one or more of the following

FIG. 9. Typical weekday load curves.

factors: type of service, i.e., whether residential, railroad, industrial, commercial, etc.; time of day; day of the week; season of the year; and weather conditions. For non-fluctuating types of demand, it is customary to plot the instantaneous demand on the hour and half-hour and to assume linear variation between plotted points. Many systems currently use recording or graphic meters that continuously record on a chart the instantaneous demand. For fluctuating demands, it is customary to plot chronological load curves showing average values of demand over 10-, 15-, or 30-min intervals. The effect of season on the variation of the load is presented in Fig. 9.

**Load-duration curves** represent the data of the chronological load curve with the ordinates rearranged in order of decreasing values. The horizontal distance of any point from the load axis indicates the duration of all loads equal to and greater than that indicated on the ordinate. The coordinates of

any point on the curve are determined by the value of the load, and the length of the horizontal line at that load level as limited by the chronological load curve. The method is illustrated in Fig. 10 for points (1) and (2). The areas under the chronological load

and load-duration curves are equal and represent the total energy for the period. For any increment of load, such as  $\Delta L$ , the corresponding areas, and hence the corresponding incremental energies represented thereby, are equal. This is represented in Fig. 10 by the cross-hatched areas.

FIG. 10. Methods of showing load.

Load-energy curve indicates the total energy for a given load and all values less than that load. In Fig. 10, the abscissa corresponding to point (4) indicates the energy for all loads equal to and less than the load indicated by the position of line  $b$ ; equivalent to the areas under the line  $b$  for both the chronological and load-duration curves. Similarly,  $\Delta E$  is the energy value corresponding to  $\Delta L$  or the cross-hatched areas. Point values for the curve are obtained from successive values of  $\Delta E$  commencing with the lowest value of load.

### 35. TERMS AND DEFINITIONS

**Load** on a machine or apparatus is the power which it delivers.

**Power** is the time rate of transferring or transforming energy.

**Energy** of a system is measured by the amount of mechanical work which the system is capable of doing.

**Demand** of an installation or system is the load at the receiving terminals averaged over a specified interval of time.

**Maximum demand** is the greatest of all demands which have occurred during a given period of time.

**Base load** is the minimum load over a given period of time.

**Connected load** of a system is the sum of the continuous ratings of the load-consuming apparatus connected to the system.

**Load diversity** is the difference between the sum of the peaks of two or more individual loads and the peak of the combined loads.

**Load coincidence** of a system is the reciprocal of its load diversity.

**Peak load** is the maximum load consumed or produced by a unit or group of units in a stated period of time. It may be the maximum instantaneous load or the maximum average load over a designated interval of time.

**Load factor** is the ratio of the average load over a designated period of time to the peak load occurring in that period.

**Plant factor** is the ratio of the average load on the plant for the period of time considered, to the aggregate rating of all the generating equipment installed in the plant.

**Capacity factor** is the ratio of the average load on a machine or equipment for the period of time considered, to the rating of the machine or equipment.

**Operation factor** is the ratio of the duration of actual service of a machine or equipment to the total duration of the period of time considered.

**Output factor** is the ratio of the actual energy output, in the period of time considered, to the energy output which would have occurred if the machine or equipment had been operating at its full rating throughout its actual hours of service during the period.

**Demand factor** is the ratio of the maximum demand of a system, or part of a system, to the total connected load of the system, or part of system, under consideration.

**Utilization factor** is the ratio of the maximum demand of a system or part of a system, to the rated capacity of the system, or part of the system, under consideration.

**Dump power** is hydro power (in excess of load requirements) made available by surplus water.

**Firm power** is power intended always to be available, even under emergency conditions.

**Prime power** is the maximum potential power constantly available for transformation into electric power.

**Cold reserve** is reserve generating capacity that is available for service but not in operation.

**Hot reserve** is reserve generating capacity that is in operation but not in service.

**Spinning reserve** is reserve generating capacity that is connected to the bus and ready to take load.

**Run-of-river station** is a hydroelectric generating station that utilizes the stream flow without water storage.

**Stream flow** is the quantity rate of water passing a given point.

# ATOMIC POWER

**FOREWORD.** Public announcement of the production of atomic power in the form of electricity or mechanical power will be another milestone in the advance of our civilization. So far, the nuclear reactors which have been publicly described are for the conversion of fertile to fissionable material, for the production of radioactive isotopes, and for experimental purposes.

It has been announced that nuclear reactors to produce useful power are under development. The sections on power conversion systems and atomic power systems are written in anticipation of the successful completion of these developments.

**Atomic Energy Act.** The Atomic Energy Act of 1946 established the United States Atomic Energy Commission and set forth the law under which it operates. All information, critical materials, research, and development activities related to atomic power are controlled in the United States by the Atomic Energy Commission. The utilization of atomic power is also controlled by the Commission. Much of the information and the data necessary to designing atomic power plants has not yet been released to the public because of their military importance.

The information and data given here are from previously published sources. It is emphasized that the data on nuclear properties of materials are presented only for illustrative purposes. More accurate and complete data exist but have not yet been released.

**Atomic Power Plant.** An atomic power plant is an equipment for accomplishing the controlled release of atomic energy to produce useful mechanical or electrical power. The equipment includes a nuclear reactor (frequently called a pile) in which neutrons cause nuclear fissions. Heat energy from the fissions is extracted and used to drive suitable heat engines (usually turbines) to produce power.

## 1. NUCLEAR PROCESSES

**THE FUNDAMENTAL PARTICLES AND RADIATION.** In describing the workings of atomic power plants, it is useful to consider that all matter consists of various arrangements of a certain few fundamental particles. They are *electron*, *proton*, and *neutron*. Other particles are known or believed to exist, such as *positron*, *neutrino*, and *meson*, but they are not principally involved in the nuclear reactions resulting in useful power and will not be treated here. However, an element of energy, the *photon*, is involved in the relationships of these particles.

**Electrons** are the lightest known particles, having a mass when at rest, of  $9.107 \times 10^{-28}$  gram, and a negative electrical charge of  $4.8025 \times 10^{-19}$  electrostatic unit. They move with extremely high velocities, usually being constrained by electrostatic forces to move in orbits about other particles of opposite charge. Electrons ejected from nuclei are known as *beta rays*.

**Protons** are much heavier particles, having a positive electrical charge of the same magnitude as the negative charge of the electron. The mass of the proton is  $1.67248 \times 10^{-24}$  gram, being 1836 times greater than that of the electron.

**Neutrons** are particles slightly heavier than protons. Neutrons carry no electrical charge, and have a mass of  $1.67472 \times 10^{-24}$  gram. It is sometimes helpful to consider the neutron as a very closely joined proton and electron whose charges cancel. Neutrons in motion are not deflected by electrostatic forces and consequently penetrate matter much more readily than charged particles.

**Photons** are quanta of electromagnetic radiation having energy related to their frequency by the equation

$$E = h\nu \quad (1)$$

where  $E$  = energy of the photon, erg;  $h$  = Planck's constant, erg sec;  $\nu$  = frequency of the photon,  $\text{sec}^{-1}$ .

In nuclear reactions, photons behave as particles traveling with the velocity of light. High-energy photons are known as *gamma rays*, and, like neutrons, are extremely penetrating.

Table 1. Properties of the Fundamental Particles

Particle	Charge, esu	Mass, Atomic Mass Units	Mass, Grams
Electron	$-4.8025 \times 10^{-10}$	0.00054862	$9.107 \times 10^{-28}$
Proton	$+4.8025 \times 10^{-10}$	1.007582	$1.67248 \times 10^{-24}$
Neutron	0	1.00893	$1.67472 \times 10^{-24}$
Photon	0	0.00107 *	$1.762 \times 10^{-27}$ *

\* Equivalent mass of 1 Mev photon.

Table 2. Some Fundamental Units of Nuclear Physics

Ma

1 mass unit =  $1.6604 \times 10^{-24}$  gram  
 =  $1/16$  mass of  $\text{gO}^{16}$  (Oxygen, see Nuclear Structure, p. 17-04)

Charge:

1 electronic charge =  $1.602 \times 10^{-19}$  coulomb  
 = charge of one electron (-) or proton (+)

Energy:

1 electron volt =  $1.602 \times 10^{-12}$  erg  
 = kinetic energy of particle, having one electronic charge, when the particle has fallen freely through a potential drop of one volt

1 Mev = one million electron volts

Planck's constant:

 $h = 6.624 \times 10^{-27}$  erg sec

Velocity of light:

 $c = 2.9978 \times 10^{10}$  cm per sec

**EQUIVALENCE OF MASS AND ENERGY.** Mass and energy are equivalent and, under certain very special circumstances, convertible from one to the other. This fact was first confirmed by observation of radioactive substances. The direction of the conversion is such that the inertial mass of a moving body increases as its speed increases. The equivalence of mass and energy is stated by the very simple Einstein equation:

$$E = mc^2 \quad (2)$$

where  $E$  = energy, ergs;  $m$  = mass, grams;  $c$  = velocity of light, centimeters per second.

It may be seen from this that a small amount of mass is equivalent to a very great amount of energy. There are several processes which accomplish the conversion of mass to energy. The most important of them, nuclear fission, is the basis of atomic power.

Table 3. Conversion Table for Energy Units

	Mev	mass units	ergs	g-cal	kw-hr	ft-lb	hp-hr

The increase in mass due to velocity, at relatively slow velocities (compared to the velocity of light), is according to the equation

$$m = \frac{m_0}{\sqrt{1 - \left(\frac{v}{c}\right)^2}} \quad (3)$$

where  $m$  = mass of moving particle, grams;  $m_0$  = rest mass of particle, grams;  $v$  = velocity of particle, centimeters per second;  $c$  = velocity of light, centimeters per second.

**ATOMIC STRUCTURE.** In matter the fundamental particles are arranged to form atoms. An atom consists of a number of closely grouped protons and neutrons surrounded by a number of electrons moving in orbits about the central nucleus of protons and neutrons.

Fig. 1. Schematic representation of the Lithium atom ( ${}^6\text{Li}$ ).

**NUCLEAR STRUCTURE.** The protons and neutrons of the nucleus are bound together by powerful forces to form a very dense and compact group. Under certain circumstances, however, these forces can be overcome and particles caused to leave the group.

The **atomic number,  $Z$** , is the number of protons in the nucleus. Since this determines the number of electrons of the atom, it identifies the chemical properties of the atom. All atoms of a given atomic number have the same chemical properties, regardless of the structure of their nucleus.

The **mass number,  $A$** , of an atom is the total number of protons and neutrons in its nucleus.

**Isotopes** are species of the same element having atoms of the same atomic number but different mass numbers.

The atomic number of an element is indicated by its name or symbol, whereas its mass number is indicated by a superscript following the symbol; for example,  $\text{N}^{14}$ . A more complete designation containing the atomic number as a prefixed subscript is sometimes used:  ${}_{7}\text{N}^{14}$ .

The actual mass of a nucleus is not the sum of the masses of the individual protons and neutrons which comprise it. Rather, the nucleus has somewhat less mass because the particles have given up some of their mass to create the **binding energy** of the nucleus.

Figure 2 shows the discrepancy per nuclear particle between the measured mass of nuclei and the sum of the masses of the individual nuclear particles. The discrepancy is greatest for elements of intermediate mass number, and these elements have the most stable nuclei, since the binding energy per particle is greatest.

**RADIOACTIVITY.** Frequently substances occur with unstable nuclei which disintegrate spontaneously. The disintegration consists of the ejection of one or several particles from the nucleus, frequently accompanied by the emission of gamma-ray photons. Such

The nucleus typically has an approximate radius of  $10^{-12}$  cm, while the electrons move in orbits averaging  $10^{-8}$  cm in radius. There are equal numbers of electrons and protons in a stable atom, and it is electrically neutral. Some of the electrons may not be strongly held in the atom, and the near-by passing or direct collision of a charged particle or absorption of a photon may dislodge an electron, leaving the atom with a net positive charge. It is then said to be ionized.

The chemical behavior of an atom is determined by its number of electrons.

The simplest atom, hydrogen, consists of one proton and one electron. One of the most complicated atoms, Uranium<sup>238</sup>, consists of 92 electrons, 92 protons, and 146 neutrons. Figure 1 is a schematic representation of the Lithium atom, which consists of 3 electrons, 3 protons, and 4 neutrons.

Fig. 2. Mass discrepancy per nuclear particle. (From Aston's data)

substances are said to be *radioactive*. If the disintegration changes the number of protons in the nucleus (and consequently the number of orbital electrons), a new chemical element is formed. The new element may also be unstable and suffer further disintegration.

The particles emitted by the nuclei may be protons, neutrons, electrons (*beta rays*), or *alpha* particles. Alpha particles are helium nuclei, consisting of two protons and two neutrons.

Some substances are naturally radioactive and may emit alpha ( $\alpha$ ), beta ( $\beta$ ), or gamma ( $\gamma$ ) rays. Many substances become artificially radioactive upon being bombarded by certain of the fundamental particles.

An example of a naturally radioactive series is

(The symbols  $y$ ,  $d$ ,  $h$ ,  $m$ , and  $s$  are used to designate year, day, hour, minute, and second, respectively, in stating the half life of the disintegrating substance.)

An unstable nucleus has a definite and characteristic statistical probability of disintegrating within a given length of time. The number of disintegrations,  $\Delta N$ , in an interval of time,  $\Delta t$ , is proportional to the total number of active nuclei  $N$ , the length of time,  $\Delta t$ , and the characteristic probability constant  $\lambda$ . Hence,

$$\Delta N = -\lambda N \Delta t \quad (4)$$

The number  $N$  of nuclei remaining of an initial number  $N_0$  after the lapse of time  $t$  is

$$N = N_0 e^{-\lambda t} \quad (5)$$

It is usual to describe radioactive emitters by their *half life*,  $T_{1/2}$ , the time necessary for half the initially present nuclei to disintegrate. In terms of the probability constant, this is

$$T_{1/2} = \frac{0.693}{\lambda} \text{ sec} \quad (6)$$

In a radioactive series the decay of the original or parent substance and the growth and decay of the resulting new radioactive substance, the daughter, are described by these equations:

$$N_1 = N_0 e^{-\lambda_1 t} \quad (7)$$

$$N_2 = \frac{\lambda_1 N_0}{\lambda_2 - \lambda_1} [e^{-\lambda_1 t} - e^{-\lambda_2 t}] \quad (8)$$

Subscript 0 refers to the initial quantity of parent substance, subscript 1 to the parent substance, and subscript 2 to the daughter substance.

If the radioactive series is such that the daughter substance decays to form a *stable* substance,  $N_3$ , the process is described by the equation:

$$N_3 = N_0 - N_1 - N_2 \quad (9)$$

or

$$N_3 = N_0 \left[ 1 - \frac{\lambda_2}{\lambda_2 - \lambda_1} e^{-\lambda_1 t} + \frac{\lambda_1}{\lambda_2 - \lambda_1} e^{-\lambda_2 t} \right] \quad (10)$$

Figure 3 represents graphically eqs. 7, 8, and 10 for a hypothetical radioactive series.

#### INTERACTION OF PARTICLES AND PHOTONS WITH MATTER.

A particle or photon passing through matter will collide, sooner or later, with an atom. In an atomic power plant, an enormous number of collisions occur every second, causing a variety of interactions. The following are of particular interest.

**Beta-ray Scattering and Absorption.** A free electron moving at any considerable velocity will dislodge other electrons from their orbits as it passes through matter. In so doing, it gives up some of its energy, and after a number of collisions is slowed down and stopped. Typically, electrons ejected from radioactive nuclei will move a few feet in air or a few hundredths of an inch through aluminum before being stopped. The incident electron is deflected or scattered by its collisions, and follows a *zigzag* path, leaving behind it a trail of ionized particles.

**Alpha Scattering and Absorption.** Alpha particles emitted by radioactive substances are very quickly absorbed by matter. They create ions by dislodging electrons, and to

Fig. 3. Hypothetical radioactive series of three elements illustrating eqs. 7, 8, and 10.

extent are scattered by collisions with nuclei. Usually the coulomb forces acting between the positively charged nucleus and the positively charged alpha particle prevent their contact. The particle is deflected, and momentum is transferred to the nucleus in the manner of a billiard-ball collision. Only the most energetic can penetrate nuclei and be absorbed to form radioactive substances. Typically, alpha particles travel a few inches in air or a few mils in solids before being stopped.

**Gamma-ray Reactions.** Gamma-ray photons are absorbed in matter by collisions with atoms. The photon may give up all its energy to dislodging an electron from its orbit (the photoelectric effect), it may give up part of its energy to the electron and the remainder to the formation of a new, lower energy gamma-ray photon (the Compton effect), or it may collide with a nucleus, resulting in annihilation of the photon and formation of two new particles, an electron and a positron (pair production). The latter process is an interesting example of the conversion of energy into mass.

The absorption of gamma radiation by materials of different density varies almost directly with the density of material. There is a considerably more complex relationship between the absorption and the energy of the gamma radiation. Generally, high-energy gamma rays are more penetrating. If radiation of intensity  $I_0$  strikes a layer of absorbing material, the intensity  $I$  at a distance  $x$  through the material is

$$I = I_0 e^{-\mu x} \quad (11)$$

where  $\mu$  is the coefficient of absorption for the material for gamma radiation of that particular energy. The absorption coefficients for gamma radiation of energy 1.3 Mev in several materials are shown in Table 4.

Table 4. 1.3-Mev Gamma-ray Absorption Coefficients

Absorber	$\mu$ (cm <sup>-1</sup> )
Carbon	.115
Aluminum	.156
Iron	.455
Copper	.509
Tin	.345

**Neutron Reactions.** Neutrons in motion are not deflected by electronic or nuclear charge forces. When a neutron collides with a nucleus, one of several reactions may occur, and there is a definite probability of each, depending upon the material and the energy of the neutron.

The colliding neutron may undergo *elastic scattering*, in which it rebounds at a random angle, with conservation of energy and momentum of the system. It may undergo *inelastic scattering*, in which it rebounds after having transmitted a considerable amount of its energy to the nucleus, leaving the nucleus in an excited condition. Or, finally, the neutron may be *captured* by the nucleus, with one of the following results:

1. ( $n - \alpha$ ) This notation indicates capture of the neutron and instantaneous emission of an alpha particle from the nucleus.
2. ( $n - p$ ) Neutron capture—proton emission.
3. ( $n - \gamma$ ) Formation of a stable isotope.
4. ( $n - \gamma$ ) Formation of an unstable isotope, which subsequently decays by beta emission.

**Nuclear Fission.** If the nuclei of certain very heavy elements —  ${}_{92}\text{U}^{235}$ ,  ${}_{92}\text{U}^{235}$ , or  ${}_{94}\text{Pu}^{239}$  absorb neutrons, the nuclei will split approximately in half, releasing a large amount of energy.

This process, known as *nuclear fission*, results in the formation of new nuclei (fission fragments) of roughly half the atomic weight of the original nuclei. The reaction also accomplishes the release of neutrons (averaging between 1 and 3) and subsequent emission of gamma-ray photons and electrons. Figure 4 represents a fundamental nuclear fission process.

Occasionally one of the neutrons is not released at the instant of fission, but rather may be ejected from a fission fragment a

short time later. These *delayed neutrons* play an important part in the controlled release of atomic energy.

When a great many fissions are taking place, the delayed neutrons appear in several

groups according to the half lives of the radioactive disintegrations causing their appearance. Table 5 gives approximate half lives and percentages of the total number of neutrons (prompt + delayed) for delayed neutrons from fissions in  $U^{235}$ .

Table 5. Approximate Half Lives and Percentages of Delayed Neutrons

$T_{1/2}$ , sec	%
55.6	.02
22.0	.14
4.51	.18
1.53	.20
0.42	.07
Total	.61

The fission fragments are elements of atomic mass ranging from 70 to 160. Many of them are radioactive. Their decay through a series of disintegrations to form stable nuclei may take months, or years.

A typical fission releases about 200 Mev of energy, which is distributed approximately as shown in Table 6.

Table 6. Approximate Distribution of Energy from Fission

Kinetic energy of fission fragments	160 Mev
Kinetic energy of neutrons	5
Prompt gamma radiation	5
Radioactive decay of fission fragments (mostly beta and gamma radiation)	20
Energy release due to ultimate absorption of neutrons from fission (neutron binding energy)	10
Total	200

**NUCLEAR CROSS SECTIONS.** The probability of a given type of nuclear reaction occurring is indicated by an equivalent cross-sectional area per nucleus,  $\sigma$ . For most substances this is a very small area, about  $10^{-24}$  cm<sup>2</sup>. *Cross sections* are frequently stated in *barns*, where 1 barn =  $10^{-24}$  cm<sup>2</sup>. The total cross section of a nucleus  $\sigma$  equals the sum of cross sections for the several nuclear reactions which can occur, such as  $\sigma_s$  (scattering),  $\sigma_c$  (capture),  $\sigma_f$  (fission).

$$\sigma = \sigma_s + \sigma_c + \sigma_f \quad (12)$$

In computing the progress of particles through matter, it is convenient to use the macroscopic cross section  $\Sigma$ , which is the total of the nuclear cross sections per unit volume, and has the dimension centimeter<sup>-1</sup>.

$$\Sigma = \sigma N \quad (13)$$

where  $N$  is the number of nuclei per unit volume. The reciprocal of macroscopic cross section is the *mean free path*  $\lambda$ .

$$\frac{1}{\Sigma} = \lambda \quad (14)$$

This is the average distance the particle can travel through the substance before it suffers a collision of the type specified by the cross section.

The nuclear cross section bears little relationship to the actual projected area of the nucleus. Rather, it is thought of as the projected area of the region within which the short-range binding forces of the nucleus can influence the passing particle to collide. If a stream of particles, such as neutrons, penetrate material in which all collisions result in capture, the intensity  $I$  is related to the incident intensity  $I_0$  (neutrons per cm<sup>2</sup> sec), and the distance traveled,  $x$  cm, by

$$I = I_0 e^{-\Sigma_c x} = I_0 e^{-x/\lambda_c} \quad (15)$$

Cross sections vary with the velocity of the incident neutron. They are generally greater for low-velocity neutrons, and often are inversely proportional to neutron velocity.

$$\sigma \sim \frac{1}{v} \quad (16)$$

Frequently, however, the variation is erratic. There may be very high capture or fission cross sections at particular neutron velocities.

**CHAIN REACTION.** If a sufficient quantity of fissionable material is assembled, enormous amounts of energy can be released by means of a chain reaction. A neutron is

absorbed, causing a fission producing several neutrons. They, in turn, are absorbed, causing fissions and producing still more neutrons. Thus the number of fissions may continue to increase tremendously. Figure 5 is a diagrammatic representation of such a chain.

There are always stray neutrons present in matter to initiate such chain reactions. They arise from cosmic-ray reactions or such radioactive effects as spontaneous fissions.

Some of the neutrons may escape without being captured. Others may be captured without causing fission. Whether or not the chain reaction continues depends upon the competition among these processes: (1) escape, (2) nonfission capture, (3) fission. If the loss of neutrons due to the first two processes is less than the surplus from the third, the chain reaction will continue.

Fig. 5. Chain reaction.

motion is random. Their energy varies from about 1 Mev to about  $1/40$  electron volt. These least energetic neutrons are called *thermal neutrons* because they are in thermal equilibrium with the matter surrounding them.

In calculating diffusion of neutrons, the behavior of the average neutron is considered in each case, and the behavior of those deviating from the average is ignored. This method is accurate because there are always sufficient numbers of events to realize the statistical probabilities involved.

**One-velocity Diffusion.** The simplest diffusion theory assumes that all neutrons have the same velocity. This is a useful theory because in many nuclear reactors most of the neutrons are at thermal energies. In such reactors, it is reasonably accurate to ignore those neutrons having greater than thermal energies.

The continuity equation for neutrons being created, scattered isotropically, and absorbed is

$$\frac{\partial n}{\partial t} = q - \frac{n}{\tau} - \text{div } j \quad (17)$$

where  $n$  = instantaneous neutron density,  $q$  = rate of neutron creation,  $\tau = 1/v\Sigma_a$  average lifetime of neutrons,  $t$  = time,  $v$  = neutron velocity,  $D = v/3\Sigma_a$  = diffusion constant,  $j = -D \text{ grad } n$  = vector current of neutrons.

In a multiplying medium, creation =  $k \times$  absorption, so for steady state  $\left(\frac{\partial n}{\partial t} = 0\right)$ :

$$\nabla^2 n + \frac{k-1}{L^2} n = 0 \quad (18)$$

$$\nabla^2 n = \frac{\partial^2 n}{\partial x^2} + \frac{\partial^2 n}{\partial y^2} + \frac{\partial^2 n}{\partial z^2} \text{ in rectangular coordinates}$$

$L$  = diffusion length

$$L^2 = D = \frac{1}{3\Sigma_a\Sigma_a}$$

$$\Sigma_a = (\text{absorption}) = \Sigma_c + \Sigma_f$$

For a *point source* of neutrons in an infinite medium which scatters and captures but does not create ( $\sigma_f = 0$ ), the distribution of neutrons is (in spherical coordinates):

$$n(r) = \frac{Qre^{-r/L}}{4\pi Lr} \quad (19)$$

where  $Q$  is the strength of the point source.

For a *plane source* (in rectangular coordinates):

$$n(z) = \frac{Qr}{2L} e^{-|z|/L} \quad (20)$$

where  $Q$  is the strength of the plane source per unit area.

These expressions apply to homogeneous media which are not strongly absorbing, in regions remote from boundaries and sources.

**Slowing Down of Neutrons.** Neutrons emitted from fissions travel with great energy until they collide with a nucleus. If it is a scattering collision, the neutron loses some of its energy and travels at a lesser velocity until another collision occurs. This collision may take more energy away. Thus, if the neutron escapes absorption, it continues to lose energy through repeated scattering collisions, until it reaches thermal equilibrium with its surroundings. The energy loss per collision is greater when colliding with light nuclei. The *average logarithmic energy loss* per collision  $\xi$  is referred to, in computing the slowing down of neutrons:

$$\xi = \left[ \ln \frac{E_{\text{before collision}}}{E_{\text{after collision}}} \right]_{\text{average}} \quad (21)$$

where  $E$  = neutron energy.

The relation between  $\xi$  and the mass of the nucleus  $M$  (in units of neutron mass) is

$$\xi = 1 - \frac{(M-1)^2}{2M} \ln \frac{M+1}{M-1} \quad (22)$$

(See Fig. 6.)

The *slowing down power* of a material,  $\xi \Sigma_s$ , is a measure of its effectiveness in reducing fast neutrons to thermal energies with a minimum number of collisions.

Any one of these collisions may result in absorption of the neutron. The probability of absorption in a given material usually depends on the neutron energy. There are many so-called *resonance absorption bands*. These are ranges of incident neutron energy for which the absorption cross section is extremely large. For example,  $\sigma_a$  for  $U^{238}$  is very high at neutron energies of a few electron volts, and  $\sigma_f$  for  $U^{235}$  is high for thermal neutrons.

To improve the accuracy of the one velocity diffusion equation the diffusion length  $L$  may be modified to account for the diffusion of neutrons slowing down as well as their diffusion after reaching thermal energies:

$$L^2 = L_{st}^2 + L_{th}^2 \quad (23)$$

The square of the *slowing down length*  $L_{st}^2$  is frequently called the *age*. It may be

calculated if the variation of scattering cross section with neutron energy is known:

$$L_{st}^2 = \int_{E_{\text{thermal}}}^{E_{\text{fission}}} \frac{3(\Sigma_s)^2 \xi E}{E} dE \quad (24)$$

Fig. 7. Elements of a nuclear reactor.

elements of a nuclear reactor are (1) fissionable material, (2) fertile material, (3) moderator, (4) coolant, (5) reflector, and (6) structural materials. (See Fig. 7 for a schematic representation of a nuclear reactor.)

Fig. 6. Average logarithmic energy loss per collision.

## 2. NUCLEAR REACTORS

Nuclear reactors are assemblies of fissionable and other materials so arranged and in sufficient quantities as to be capable of supporting a chain reaction. They may be used to produce useful power and to create new fissionable material. The basic elements

**FISSIONABLE AND FERTILE MATERIALS.** The important *fissionable materials* are

Uranium  ${}_{92}\text{U}^{235}$   
 Plutonium  ${}_{94}\text{Pu}^{239}$   
 Uranium  ${}_{92}\text{U}^{233}$

The important *fertile materials* are

Uranium  ${}_{92}\text{U}^{238}$   
 Thorium  ${}_{90}\text{Th}^{232}$

All of them are extremely heavy metals, quite active chemically, having relatively poor engineering properties. They may be used in nuclear reactors in metallic form, as oxides, carbides, or in alloys with other metals.

Natural uranium is a mixture of  ${}_{92}\text{U}^{235}$  and  ${}_{92}\text{U}^{238}$  in the proportion  $\frac{\text{U}^{235}}{\text{U}^{238}} = \frac{139}{1}$ .

$\text{U}^{235}$  has a relatively large probability of absorbing neutrons to produce fissions. The fission cross section  $\sigma_f$  exists at all neutron energies but is greatest at thermal energies ( $\sigma_f \cong 500$  barns).

$\text{U}^{238}$  undergoes spontaneous fission at a very slow rate and also has a small probability of undergoing fission upon absorption of very high-energy neutrons. Neither of these fission reactions is of primary importance in maintaining chain reaction.

However,  $\text{U}^{238}$ , upon absorbing a low-energy neutron, undergoes a series of radioactive disintegrations leading to a new fissionable material. The following is a statement of the process:

Plutonium,  ${}_{94}\text{Pu}^{239}$ , is a fissionable material which disintegrates at a slow rate, by alpha emission. It is important that plutonium, being different chemically from  $\text{U}^{238}$ , may be separated by chemical means.

Thorium,  ${}_{90}\text{Th}^{232}$ , is another fertile material. Upon absorbing a neutron it decays to form the fissionable isotope of uranium,  ${}_{92}\text{U}^{233}$ . The following is a statement of the process:

This uranium isotope may be chemically separated from the thorium.

Some nuclear reactors require a relatively pure concentration of fissionable material. In order to separate  $\text{U}^{235}$  from  $\text{U}^{238}$  for this purpose, several systems have been developed. The *gas diffusion separation* method utilizes the fact that the lighter isotope  $\text{U}^{235}$ , when part of a gas molecule, will penetrate a porous membrane more readily than the heavier isotope,  $\text{U}^{238}$ . The *electromagnetic separation* method employs the principle of the mass spectrometer to separate uranium isotopes. Both methods require extremely elaborate and expensive equipment. Other methods such as thermal diffusion and centrifuging have been developed to some small extent.

The chemical separations of  $\text{Pu}^{239}$  from  $\text{U}^{238}$  and of  $\text{U}^{233}$  from  $\text{Th}^{232}$  are more readily accomplished than the mechanical separation of  $\text{U}^{235}$  from  $\text{U}^{238}$ . Largely for this reason it is expected that the conversion of fertile material will be the more important method of producing concentrated fissionable material in the future.

**MODERATOR.** The probability of neutron collisions to produce fission is greater for thermal neutrons. For this reason a *moderator* is used in many nuclear reactors to slow down the neutrons to thermal energy. The moderator is a material of low atomic weight and very low-capture cross section. It is usually distributed through the reactor in such a way that high-energy neutrons emerging from fissions undergo numerous collisions within the moderator before encountering any fissionable or fertile material. The neutron loses more energy in colliding with a light nuclei than with a heavy one. Hence, in a moderator, fewer collisions are required to slow the neutron down to thermal energy. As a result, it has a much greater likelihood of escaping capture during the slowing process.

The most usual moderators are carbon, beryllium, or beryllium oxide, "heavy water" ( $\text{D}_2\text{O}$ ) and ordinary water ( $\text{H}_2\text{O}$ ). In a carbon-moderated reactor the neutrons undergo approximately 100 collisions in slowing down to thermal energies (for carbon  $\xi = 0.15$ ).

**COOLANT.** In a nuclear reactor the energy which may be converted into useful power appears first in the form of kinetic energy of the fission fragments, neutrons, and beta and gamma radiation. Subsequent collisions of these particles with the material of the reactor very quickly convert the energy into thermal agitation of the atoms collided with. Thus the energy released by fissions must be extracted in the form of sensible heat.

Any of the methods of heat transfer may be used to accomplish this heat extraction,

including radiation, conduction, free convection, and forced convection. Forced convection of a coolant fluid through channels in the nuclear reactor is most frequently employed. The coolant is heated upon passing through the reactor, and may leave at a relatively high temperature, permitting efficient utilization of the heat to drive a heat engine.

The coolant may have some effect on the chain reaction, since it may contribute to the scattering, slowing down, and capture of neutrons. The most desirable coolants have low-capture cross sections, good heat-transfer characteristics, and low tendency to corrode. Gases, such as air and helium, or liquids, such as water and mercury, may be used.

**REFLECTOR.** Some of the neutrons in a reactor may escape completely and hence make no contribution to continuing the chain reaction. To reduce this leakage loss, the reactor core may be surrounded with a reflector. This is a layer of material having a relatively large scattering cross section and small absorption cross section. Many neutrons leaving the core encounter scattering collisions in the reflector and are directed back into the core. These returned neutrons may cause fissions. Thus an assembly surrounded by a reflector requires less fissionable material to chain react.

Lead, carbon, and beryllium are typical reflector materials.

**STRUCTURAL MATERIALS.** Fissionable and fertile materials do not have sufficient strength and durability to form the mechanical structure of a reactor. Neither do many of the moderators and reflectors. For this reason it is necessary to employ some structural materials in the reactor. They may be used to support the fissionable material and other materials, to protect them from the corroding or eroding action of the coolant, and to provide means for manipulating them in controlling or refueling the reactor.

Structural materials must have adequate strength and durability and must have low absorption cross sections. Most organic materials and many other compounds are not suitable because of their inability to withstand the tremendous bombardment of neutrons and radiation in the reactor. Aluminum and iron have been used.

**REACTIVITY.** If a large number of fissions occur simultaneously in a typical nuclear reactor, the life history of the resulting group of neutrons is as follows.

A very few neutrons are absorbed quickly to cause *fast fissions*, slightly increasing the number of neutrons in the group. The neutrons are slowed down by predominately inelastic collisions while at high energies, and elastic collisions at lower energies. During the slowing down some of the neutrons suffer resonance capture in fertile material. After attaining thermal energy, the remaining neutrons continue to diffuse until they are absorbed to produce fissions or are captured by the impurities, structural materials, or other nonfissionable materials in the reactor. During the slowing down and thermal diffusion, some neutrons escape from the reactor. Those producing fissions cause a new group of neutrons, and the life cycle repeats.

The ratio of neutrons in the new generation to those in the old generation is called the *reactivity* or *multiplication constant*,  $k$ . For an infinite medium (no escape), the reactivity is

$$k = \epsilon p f \eta \quad (25)$$

where  $\epsilon$  = fast fission multiplication factor,  $p$  = resonance escape probability,  $f$  = thermal utilization,  $\eta$  = number of neutrons released per neutron absorbed in  $U^{235}$ .

**Fast fission multiplication**,  $\epsilon$ , depends on the manner in which the fissionable material is distributed in the reactor. In thermal reactors, the material is frequently arranged in lumps or rods surrounded by moderator. In them the fission neutrons very quickly encounter moderator and are slowed down before producing fast fissions. Therefore,  $\epsilon$  is usually only very slightly greater than 1. A typical value is  $\epsilon = 1.03$ .

**Resonance escape probability**  $p$ , may be computed from data on the cross sections of materials in the reactor. It expresses numerically the likelihood of a fast neutron reaching thermal energy before being captured. It takes into account the variation of cross sections with energy of the neutrons, and the relative proportions of scattering nuclei (mostly moderator) and absorbing nuclei (mostly fertile material). For a homogeneous mixture of fertile material  $U^{238}$  and moderator, C,

$$p = e^{-\int_{E_{\text{thermal}}}^{E_{\text{fast}}} \frac{\Sigma_c(U^{238})}{\Sigma_c(U^{238}) + \Sigma_s(C)} \frac{dE}{E}} \quad (26)$$

In this expression  $\Sigma_c(U^{238})$  and  $\Sigma_s(C)$  vary with neutron energy  $E$  in a manner which must be determined experimentally.

For typical ratios of moderator to fertile material (300 to 1000 atoms of carbon per atom of  $U^{238}$ ) the resonance escape probability is of the order of 0.6 to 0.9.

**Thermal utilization**,  $f$ , is the probability that thermal neutrons will be absorbed to produce fissions. Competing with this are nonfission absorptions in fertile materials and other materials in the reactor. In a homogeneous mixture, the thermal utilization is

simply the ratio of fission cross section to total absorption cross section:

$$f = \frac{\Sigma_f(U^{235})}{\Sigma_f(U^{235}) + \Sigma_a(U^{235}) + \Sigma_a(C + \text{other materials})} \quad (27)$$

Typically, the thermal utilization varies from 0.8 to 0.5.

Note that  $f$  increases when the relative proportion of moderator is decreased. The reverse is true of  $p$ . To obtain maximum reactivity a mixture must be selected to give the optimum balance between  $p$  and  $f$ .

**Number of Neutrons per Neutron Absorbed in  $U^{235}$ .** The number of neutrons released per neutron absorbed in  $U^{235}$ ,  $\eta$ , is an inherent property of the fissionable material, and must be determined experimentally. On the average,  $\eta$  is between 1 and 3.

**CRITICAL SIZE AND MASS.** In an infinite medium, chain reaction will occur when  $k = 1$ . However, in a reactor of finite size, some neutrons escape from the surface. Hence,  $k$  must be somewhat greater than one to replace the neutrons lost by leakage. As the size of the reactor is increased, the ratio of surface to volume decreases, so that the relative effect of neutron leakage grows less. For every mixture having  $k > 1$  there is a *critical size* at which the leakage is just compensated by the excess reactivity ( $k - 1$ ). This size may be computed from the diffusion equation:

$$\nabla^2 n + \frac{k - 1}{L^2} n = 0 \quad (18)$$

When the boundary condition that  $n = 0$  at the surface of the reactor is applied (a so-called bare reactor) the following expressions for critical size  $a$  and neutron distribution  $n$  obtain:

1. Cube having length of side  $a$ :

$$a_{\text{crit}} = \left[ \frac{3\pi^2 L^2}{k - 1} \right]^{1/2} \quad (28)$$

$$n = n_0 \sin \frac{\pi x}{a} \sin \frac{\pi y}{a} \sin \frac{\pi z}{a} \quad (29)$$

2. Sphere having radius  $a$ :

$$a_{\text{crit}} = \left[ \frac{\pi^2 L^2}{k - 1} \right]^{1/2} \quad (30)$$

$$\sin \frac{\pi r}{a} \quad (31)$$

3. Cylinder having radius  $a$  and length  $2a$ :

$$a_{\text{crit}} = \left[ \frac{\left( \frac{1}{4} \pi^2 + 2.4 \right) L^2}{k - 1} \right]^{1/2} \quad (32)$$

$$n_0 J_0 \left( 2.4 \frac{r}{a} \right) \cos \frac{\pi z}{a} \quad (33)$$

where  $n_0$  = neutron density at center of reactor,  $J_0$  = Bessel's function.

The boundary condition assumed in these solutions is slightly in error, and leads to values of  $a_{\text{crit}}$  which are a little too great. The curve of neutron distribution near a free surface (Fig. 8) is such that if it were extended it would reach zero at a point some distance outside the surface. This so-called *extrapolation distance*  $d$  is related to the properties of the material from which the neutrons are escaping:

$$d = 0.71 \lambda_s \quad (34)$$

where  $\lambda_s$  is the mean free path for scattering. This correction is readily applied to the values of critical dimension for bare reactors obtained from eqs. 28, 30, and 32.

In many practical reactor designs,  $k$  is only very slightly greater than one. It increases with concentration of fissionable material. It decreases with addition of fertile material, structural material, and other nonfissionable absorbers. Within limits  $k$  increases with the addition of moderator. However, as was pointed out, there is an optimum amount of moderator to give the most effective balance of  $p$  and  $f$ .

The reactivity,  $k$ , is decreased by diluting the reactor to provide space for the heat-

FIG. 8. Extrapolated end point of neutron distribution.

removing coolant. Reductions of  $k$  make necessary increased reactor size and consequently increased mass of fissionable material.

If the reactor is surrounded by a reflector, fewer neutrons leak out, and the critical size is reduced. The saving depends on type and thickness of the reflector and size of the reactor.

**REACTOR DYNAMICS.** To control the release of energy in a nuclear reactor, it is necessary to control the rate at which fissions occur. This rate is proportional to the density of neutrons. Control is made possible by building the reactor to have somewhat greater excess reactivity than is necessary to make up for the leakage of neutrons. In steady-state operation this additional reactivity may be compensated by several methods, such as the introduction of absorbing material in the reactor or moving portions of the reflector to permit greater leakage.

When it is desired to increase the power output, some of the compensation is removed, permitting the number of neutrons to increase. When it is desired to decrease the power output, extra compensation is applied, and the number of neutrons decreases.

A typical neutron appears promptly at the instant of fission, undergoes slowing down collisions, and diffuses about until absorbed to produce another fission. It may experience as many as 200 collisions. The lifetime of this neutron is of the order of one or two thousandths of a second.

A few neutrons (about  $1/2\%$ ) are delayed in appearing after the fission, so that their effective reproduction time may be very much longer than that of the prompt neutrons. These delayed neutrons have an important bearing on the rate of increase or decrease in neutron density.

When, in the operation of the reactor at steady state, a change in reactivity  $\Delta k$  is created by means of the controls, the neutron density will increase or decrease with time approximately according to the expression

$$n \cong n_0 e^{t/T} \quad (35)$$

where  $n$  = neutron density,  $n_0$  = initial neutron density,  $T$  = reactor period related to  $\Delta k$ , and  $t$  = time after change in reactivity  $\Delta k$ .

The relationship between  $\Delta k$  and the period  $T$  is very approximately expressed as follows:

$$\Delta k \cong \frac{\tau}{T} + \frac{\beta \tau_d}{T + \tau_d} \quad (36)$$

where  $\tau$  = average prompt neutron lifetime,  $T$  = reactor period,  $\beta$  = fraction of neutrons per generation which are delayed (approx. 0.005),  $\tau_d$  = average time delay in appearance of delayed neutrons (approx. 10 sec).

From this equation it will be seen that when  $\Delta k < \beta$  the reactor period  $T$  will be large, making it possible to actuate control mechanisms with enough speed to prevent a runaway condition. The physical explanation is that the significant effect of this small change in reactivity does not appear until the new delayed neutrons are released several seconds after the change was made.

On the other hand, if  $\Delta k > \beta$  the reactor period will be very small, causing the neutron density to increase or decrease so rapidly as to make control extremely difficult. The reason for this is that when  $\Delta k > \beta$ , the reactor becomes chain reacting on the prompt neutrons alone. Since the generation time of prompt neutrons is very short, extremely rapid multiplication will ensue.

Because of thermal expansion of materials and changes of average neutron velocity with temperature, the reactivity will vary with temperature changes. The *temperature coefficient*  $C$  is the constant relating reactivity and temperature,  $\Delta k = C \Delta \text{temperature}$ . For stable operation it must be zero or some negative value. A positive temperature coefficient may lead to an uncontrollable increase in reactivity. The value of temperature coefficient depends on the relative proportions of fuel, moderator, and other materials, and the manner in which heat is removed.

**REACTOR TYPES.** Reactors may be classified in several ways. One relates to the physical nature of the fuel (fissionable material), i.e., *solid fuel*, *liquid fuel*, *gaseous fuel*. Another relates to the manner in which the materials of the reactor are distributed, i.e., *homogeneous* or *heterogeneous*. Still another describes the energy of neutrons causing the fissions in the reactor, i.e., *thermal*, *fast*, or *intermediate* reactor.

**Solid fuel reactors** have fissionable material in the form of rods, plates, or lumps. It may be in concentrated form or it may be mixed or alloyed with fertile, moderator, or structural materials.

**Liquid fuel reactors** may have the fissionable material in the form of a salt such as uranyl sulfate dissolved in water (the moderator).

**Gaseous fuel reactors** are largely a matter of conjecture at present. The very dilute

concentration of fissionable materials in such a reactor would make necessary a tremendous size to attain criticality.

**Homogeneous reactors** have an intimate and uniform mixture of fissionable, fertile, moderator, and structural materials. Certain liquid fuel reactors are of this type. The performance of such reactors is amenable to calculation, since the macroscopic cross sections are uniform throughout the reactor core.

Fig. 9. Neutron distribution in a lattice cell.

from the cell. If the reactivity of the cell can be determined, the critical size of the reactor may be calculated. This is done by assuming that the reactor is made up of a homogeneous medium having properties which would give the same  $k$  as was determined for the cell.

In **thermal reactors** almost all fissions are caused by neutrons at thermal energy. Most of the foregoing description pertains to reactors of this type.

In **fast reactors** most of the fissions are caused by fast neutrons. Such reactors contain no moderator. The fuel must be highly concentrated, and more fuel is required for criticality than in thermal reactors. This is because fission cross sections are very much smaller for fast neutrons than for thermal neutrons. Fast reactors lose many neutrons by leakage, and a reflector is necessary to reduce the amount of fuel required.

**Intermediate reactors** are reactors in which most of the fissions are caused by neutrons of energy somewhere between fast and thermal. Some moderator is used. The critical mass is less than that of a fast reactor and more than that of a thermal reactor having the same rating. Figure 10 compares the energy distribution in the three types of reactors.

**REACTOR DESIGN.** Reactors are designed according to the amount of power they are to produce and whether or not they are to convert fertile material. The desired power rating and maximum permissible temperatures determine the amount of heat transfer surface required to carry heat away from the fuel. This surface, in turn, fixes the volume necessary for the coolant. The resulting dilution of the structure, together with a consideration of the amount of moderator and structural material required, determine the macroscopic nuclear properties of the reactor. With these, the critical size and mass are determined.

Important structural features to be considered in reactor designs are these.

**Fuel Structures.** The fissionable material must be so arranged that it may be removed and replaced many times during the lifetime of the reactor. It must be protected from corrosion and erosion of the coolant stream. It must be contained so that radioactive fission fragments cannot leave the fuel and enter the coolant stream.

Frequently lumps or rods of fuel are jacketed with a metallic sheath. The coolant flows around the outside of the jacket to carry away the heat generated in the lump. To maintain effective heat removal, the jacket must be in intimate contact with the fuel.

In **heterogeneous reactors** the reactor materials are separated. In them the diffusion and absorption of neutrons are markedly affected by the varying scattering and absorption cross sections of the media encountered. For example, the fuel and fertile materials are frequently arranged in lumps embedded in a matrix of moderator.

The lumps and surrounding moderator in a series of cells form a *lattice* structure as shown in Fig. 9.

If fuel and fertile material are mixed in the lumps, as is the case in natural uranium, the lump emits fast neutrons from fissions and absorbs most of the thermal neutrons that penetrate it. Thus the density of fast neutrons is greatest at the lump and least in the moderator near the cell boundary. Conversely, the density of thermal neutrons is greatest near the cell boundary and least at the lump.

It is usual to calculate the reactivity of a single cell of the lattice structure, assuming no leakage of neutrons

Fig. 10. Energy distribution of neutrons causing fissions in thermal, intermediate and fast reactors.

**Core structures** must be designed to hold the fuel elements in position. Channels and manifolding must be provided for the coolant. The moderator must be supported. The structure must be capable of withstanding the terrific bombardment of neutrons which exists in a reactor. It must withstand thermal stresses, corrosion, and erosion. It must have adequate strength at the high temperature necessary for efficient utilization of heat evolved. Means must be provided for removing and replacing the fuel elements.

**Fertile Material.** If the fuel consists of natural or somewhat enriched uranium, the fertile material and fuel will be distributed together throughout the reactor core. In a reactor utilizing highly concentrated fuel, it may be advantageous to dispose the fertile material around the outside of the reactor core and reflector. In this way neutrons escaping through the reflector may be absorbed in the fertile material.

**Control** of the reactor may be accomplished by inserting and moving neutron absorbers. Boron-coated steel rods are frequently used. In a reactor where neutron leakage is an important loss, the control may be accomplished by moving sections of the reflector to permit more or less neutrons to escape. A third means of control is to move a portion of the fuel into or away from the reactor core.

In order to control a reactor it is necessary to know the instantaneous rate of power generation or the density of neutrons in the reactor. This measurement is frequently accomplished by detectors giving an output of electrical energy related to neutron density. One type of detector utilizes the reaction of a neutron penetrating a boron nucleus in a gas. The capture leads to emission of an energetic alpha particle which in turn creates ions in the gas. The charges are collected on electrodes so that the result of the neutron absorption is a pulse of electrical current. Such a device is called an *ion chamber*.

Suitable equipment must be provided to interpret measurements of neutron density and actuate control rods to maintain the desired power output.

**Biological Shield.** The core of a nuclear reactor emits a tremendous flux of neutrons, beta rays, and gamma rays. Exposure to such flux will quickly kill any living thing. For this reason the reactor must be surrounded by a *biological shield* which will absorb these radiations.

Biological shields may be constructed of many materials, but they must be selected so as to accomplish the absorption of all types of radiation emanating from the reactor. For example, lead, which effectively absorbs gamma radiation, scatters neutrons but does not absorb them strongly. Ordinary concrete is widely used as a biological shielding material. Typical concrete shields are several feet thick.

Radiation, particularly neutrons, has a great tendency to leak through holes or cracks in shielding; hence the shield must be designed to prevent this. Furthermore, it must be gastight because gas or air leaking out of the reactor may be dangerously radioactive.

It is not possible for persons to enter or reach into the reactor, because of the radioactivity. All operations, such as moving control rods or refueling, must be accomplished by remotely controlled mechanisms.

The reactor coolant is exposed to neutron flux in passing through the reactor. If it continuously recirculates, it may become dangerously radioactive, necessitating shielding the external machinery such as pipes, heat exchangers, or turbines through which it passes.

### 3. POWER CONVERSION

The power-conversion system in an atomic power plant is used to convert heat from the nuclear reactor to electrical power or useful shaft work. This may be done by using the heated reactor coolant to drive a heat engine or by transferring heat from the reactor coolant to another fluid, used to drive the engine, as in Fig. 11.

An example of the first system is a gas-cooled reactor in which the coolant drives a gas turbine (Fig. 12a). Another possibility, involving considerable difficulties, is use of a liquid

FIG. 11. Schematic representation of an atomic power plant.

Fig. 11. Schematic representation of an atomic power plant.

coolant, such as water or mercury, which is evaporated in the reactor, and used to drive a turbine (Fig. 12b).

An example of the second system is a gas or liquid metal cooled reactor in which the

FIG. 12a. Power-conversion systems.

coolant passes through a heat exchanger to generate steam. The steam is used to drive a conventional steam turbine-generator set (Fig. 12c).

It does not appear likely that a direct conversion of atomic energy to useful power can be attained very soon because most of the energy released is in the form of kinetic energy of the fission fragments. These fragments are stopped quickly by collisions, converting the energy to heat. Even if it were possible to cause fissions in a gaseous media so that the fragments would travel farther, their direction would be perfectly random. All schemes to direct them so as to produce a net thrust or to generate electrical potential seem prohibitively inefficient.

FIG. 12b. Open-cycle steam turbine power-conversion system.

also withheld. For this reason only very general estimates can be given about the economics and possible ultimate extent of atomic power.

Thorium and uranium are widely but thinly dispersed in the earth's crust. Unlike iron, copper, and many other metals, they do not occur in concentrated deposits. The processes for recovering and refining uranium and thorium are difficult and expensive. The amount of metals made available for atomic power plants in the future depends very greatly upon improving these processes. As they are improved, it will become economically feasible to mine and refine large amounts which are now too thinly distributed to recover.

Generally, it can be said that the total energy available from complete utilisation of presently mineable uranium and thorium in the world is at least of the same order of magnitude as the energy available in the world's reserves of coal and oil.

It is expected that the initial cost of atomic power plants will be greater than the cost

#### 4. ATOMIC POWER SYSTEMS

Accurate information as to the quantity of fissionable and fertile material in the world is not available for public release. Neither are data on the cost of preparing these materials for use. The cost of building and operating atomic power plants is

FIG. 12c. Closed-cycle steam turbine power-conversion system.

of equivalent coal-burning power plants. The cost per kilowatt-hour produced is expected to be in the range of that produced by the more expensive grades of coal.

To utilize this tremendous store of energy, it will be necessary to operate reactors which not only create power but also produce more fissionable material than they consume. Such *primary reactors* might supply fuel to *secondary reactors*, which produce only power.

In addition to reactors and power-conversion equipment, *reprocessing plants* are required to separate unconsumed fissionable material from fission products. Fuel thus separated may be refabricated into fuel elements and returned to the nuclear reactor. Other reprocessing plants separate new fissionable material from partially converted fertile material and prepare both to be returned to reactors. (See Fig. 13.)

The material handled in these plants is intensely radioactive due to the large number of fission fragments contained. The work of dissolving the material and carrying out the chemical separations is done by remotely controlled apparatus behind biological shields. Elaborate and costly equipment is required. It is possible, however, for one reprocessing plant to serve several reactors, considerably reducing the reprocessing cost per reactor.

**MOBILE POWER PLANTS.** The size and weight of shielding required in atomic power plants at present limit their application. While size is not a serious handicap in land plants, it means that only the larger ships or aircraft can be considered feasible for atomic propulsion. Developments for these applications are being carried on. Even after the technical problems have been solved, it is likely that the high cost of atomic power plants will prohibit their use in smaller vehicles.

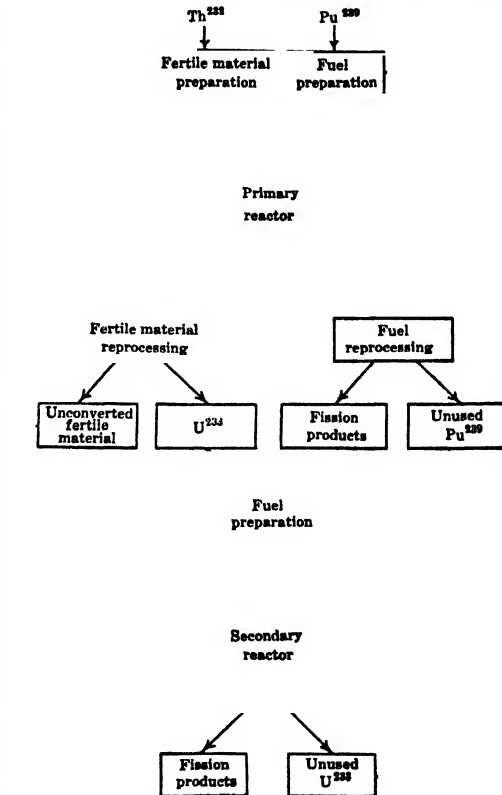

Fig. 13. Elements of an atomic power system using Plutonium and Thorium.

## 5. HEALTH PHYSICS

The measurement and control of radiation to protect the health of operating personnel are important in every phase of atomic power work. This highly developed science is called *health physics*.

Extremely small amounts of radiation are harmful, when repeated daily over long periods of time. Extremely small amounts of radioactive substances, such as uranium or plutonium, are deadly when taken into the body, as by breathing contaminated air or putting contaminated things in the mouth.

Very sensitive instruments have been developed to detect these hazards. Health physicists continually survey the air, earth, and water in the vicinity of atomic power plants and reprocessing plants, to determine whether or not they are becoming contaminated. The shielding of reactors and other equipment for handling radioactive materials is continually observed to discover and eliminate leakage of radiation. Persons working

in these areas carry with them small radiation-detecting devices which indicate the occurrence of an inadvertent exposure.

One such detector is a small piece of sensitive photographic film in a light-tight container worn as a badge. These films are carried every day and periodically developed. Beta rays, gamma rays, and neutrons tend to expose the film. An estimate of the radiation received by the person can be made from the degree of exposure shown by the developed film.

The radioactivity of a source is measured in *curies*.

$$1 \text{ curie} = 3.7 \times 10^{10} \text{ disintegrations/sec}$$

The damaging power of radiation is believed due to its creation of ions in living matter. The measure of quantity of gamma radiation is the roentgen, r. One roentgen of gamma radiation produces 1 esu of charge (on ions of either sign) per cu cm of air (NTP). It is

widely accepted that the maximum permissible gamma-ray exposure per 8-hour day should be 0.1 r.

Other types of radiation, such as beta rays or neutrons, are measured in terms of the equivalent quantity of gamma radiation, rep (roentgen equivalent physical), required to produce the same ionization.

# MEASUREMENT OF PROCESS VARIABLES

## 1. METHODS OF MEASURING TEMPERATURE

The thermodynamic temperature scale was defined by Kelvin as follows. The absolute values of two temperatures are to each other in the ratio of the heat supplied to the heat rejected in a reversible thermodynamic engine, working with a source and a refrigerator at the higher and lower temperatures, respectively. The interval between the freezing and boiling points of pure water is 100 C, giving the size of the unit degree. The scales in practical use are in general agreement with the thermodynamic scale or differ from it by small known quantities.

The fixed points of the International Temperature Scale are given in Table 1. Above 1945 F (1063 C) the scale is defined by a formula for the radiation of a black body. For all practical purposes one degree Kelvin is the same as one degree centigrade on the International Scale.

**Table 1. Fixed Points of International Temperature Scale**

Equilibrium at Standard Pressure of	Temperature	
	°C	°F
Oxygen, liquid-gas	-182.97	-297.35
Ice and water	0.000	32.00
Steam and water	100.000	212.00
Sulfur, liquid-vapor	444.60	832.28
Silver, solid-liquid	960.8	1761.
Gold, solid-liquid	1063.	1945.

The temperature scales in industrial use are given in Table 2. The Kelvin scale is the centigrade absolute scale. The Rankine scale is the Fahrenheit absolute scale. Both scales assign 0 degrees as absolute zero.

**Table 2. Common Temperature Scales**

Name	Abbreviation	Water at Standard Conditions		
		Freezing Point	Boiling Point	Intervals
Fahrenheit	F	32.00	212.00	180
Centigrade	C	0.00	100.00	100
Kelvin	K	273.16	373.16	100
Rankine	R'	491.69	671.69	180
Réaumur	R	0.00	80.00	80

**Conversion** from one temperature scale to another is accomplished by these formulas: To convert Fahrenheit to centigrade:

$$T_F = (T_C + 40) \times \frac{9}{5} - 40 = 1.8(T_C + 40) - 40$$

To convert Fahrenheit to Rankine:

$$T_{R'} = T_F + 459.69$$

To convert centigrade to Fahrenheit:

$$T_C = (T_F + 40) \times \frac{5}{9} - 40 = 0.556(T_F + 40) - 40$$

To convert centigrade to Kelvin:

$$T_K = T_C + 273.16$$

where  $T_F$  = temperature in degrees Fahrenheit,  $T_C$  = temperature in degrees centigrade,  $T_{R'}$  = temperature in degrees Rankine,  $T_K$  = temperature in degrees Kelvin.

Conversion between Fahrenheit and centigrade scales is facilitated by Tables 3 and 4. **EXPANSION THERMOMETERS.** Expansion thermometers operate on the principle

Table 3. Temperature Conversion—Centigrade to Fahrenheit

that the expansion of solid, liquid, or gas is proportional to temperature. The types are liquid-in-glass thermometer, bimetallic expansion thermometer, and transmitting expansion thermometer. Ordinary industrial temperature ranges of these thermometers are given in Table 5.

Liquid-in-glass thermometer employs the thermal expansion of mercury or other liquid

Fig. 1. Industrial mercury-in-glass thermometer.

such as alcohol. The laboratory-type thermometer usually has a bare glass stem and is calibrated for full immersion of the mercury thread or for partial immersion. The industrial-type thermometer is contained in a metal casing, as shown in Fig. 1. They are available in a wide variety of styles and temperature ranges.

Bimetallic thermometers employ the thermal expansion of a bimetal, i.e., two metals such as Invar, having a very low temperature coefficient of expansion, and brass, having a relatively high temperature coefficient of expansion, are welded together in a strip. Changes of temperature cause the bimetal strip to deflect. Bimetal thermometers ordinarily have a circular dial rather than a linear scale. They are available in a wide variety of styles and temperature ranges.

Transmitting expansion thermometers employ the thermal expansion of a liquid, the pressure-temperature relationship of a gas at substantially constant volume, or the vapor-pressure temperature relationship of a liquid. These three types are (1) liquid expansion, (2) gas expansion, and (3) vapor-actuated.

All types are constructed with a bulb connected by a length of metal capillary tubing to an instrument case as indicated in Fig. 2. A bourdon tube, spiral, or helix serves to

Fig. 2. Typical pressure thermometer.

Table 5. Useful Temperature Range of Thermometers

Type	Lower Limit, °F	Upper Limit, °F
Liquid-in-glass		
Mercury	-40	950
Alcohol	-100	250
Bimetallic	-40	800
Transmitting-expansion		
Liquid (mercury)	-40	1000
Gas (nitrogen)	-200	800
Vapor *	-50	600

\* Depends upon filling media. Full range not covered by any one filling medium.

convert the fluid pressure (expansion) into a motion for operating an indicating mechanism. The distance between bulb and instrument may be as great as 200 ft. The instrument may be:

1. Eccentric indicating, in which a pointer operates over a circular scale less than 180 geometrical degrees in extent.
2. Concentric indicating, in which a pointer operates over a circular scale more than 180 geometrical degrees in extent.
3. Recording, in which a pen operates on a circular recording chart.

The liquid-expansion thermometer nearly always employs mercury, the mercury completely filling the bulb, capillary, and bourdon tube. Often acetone, ethyl alcohol, ethyl ether, toluene, and water are used.

The gas-expansion thermometer nearly always uses nitrogen, but carbon dioxide and hydrogen are also used.

The vapor-actuated thermometer may use aniline, *n*-butane, ethyl alcohol, ethyl chloride, ethyl ether, *n*-hexane, methyl chloride, propane, sulfur dioxide, toluene, or water, depending upon the operating range desired.

**IMPORTANT CHARACTERISTICS** of the various transmitting expansion thermometers are noted in Table 6.

Table 6. Characteristics of Transmitting Expansion Thermometers

Characteristics	Mercury	Gas	Vapor
Scale shape (as used)	Linear	Linear	Nonlinear
Smallest span, °F approx.	100	160	80
Largest span, °F approx.	1000	800	350
Ambient effect	Yes	Yes	No
Cross-ambient effect	No	No	Yes
Head effect	No	No	Yes
Dip effect	Yes	No	No

A scale is linear if all temperature intervals are represented by equal incremental distances on the scale. The vapor-actuated thermometer does not have a linear scale since its shape depends upon the vapor-pressure versus temperature relationship of a liquid.

**Span** of a thermometer denotes the temperature interval between the lowest calibrated point and the highest calibrated point on the scale. The vapor-actuated thermometer can usually be made with the smallest span while the mercury thermometer can be made with the largest span.

**Ambient effect** in a transmitting thermometer is caused by variations in ambient temperature at or along the capillary or the bourdon tube. Ambient temperature changes do not affect the operation of the vapor-actuated thermometer because, by the nature of its operation, only the temperature which exists at the free surface of the liquid influences the vapor pressure in the system. This thermometer is constructed and filled in such a manner that the free surface of the liquid is always in the bulb. Ambient temperature changes affect the operation of the mercury- and gas-expansion thermometers. The mercury-expansion thermometer must usually be compensated either at the capillary or at the instrument case or both, depending upon the magnitude of ambient temperature changes, the span and operating temperature of the thermometer, and the length of capillary. Like the mercury-expansion thermometer, the gas-expansion thermometer sometimes requires compensation, but the ambient effect is not generally so large because the bulb volume and temperature span of the gas-expansion thermometer are usually large.

**Cross-ambient effect** exists only in the vapor-actuated thermometer and when the span of the thermometer is from below ambient to above ambient temperature. Then, when the measured temperature crosses the ambient temperature, a physical transfer of fluid between the "hotter" and the "colder" spaces in the thermometer system must take place, causing a serious delay in the operation of the thermometer.

**Head effect** exists only in the vapor-actuated thermometer and when the thermometer bulb is placed at a substantially higher or lower position (elevation) than that for which the instrument was calibrated. The head of liquid in the capillary adds to or subtracts from the vapor pressure in the thermometer system and thereby causes an error. This error is avoided by calibrating the thermometer with the bulb in the position in which it is to be used.

**Dip effect** exists mainly in the mercury thermometer and when the thermometer bulb is suddenly immersed in a fluid having a different temperature from the bulb. Because the metal casing of the bulb expands or contracts more quickly than the mercury, the

thermometer may momentarily indicate a reversed change in temperature. This effect is not serious in the industrial use of the thermometer.

**THERMOMETER WELLS.** All expansion thermometers may be installed with a thermal well (as shown in Fig. 3) surrounding the thermometer bulb. Whenever possible, a thermometer bulb should be in direct contact with the substance whose temperature is being measured. When a thermometer well is necessary, all exposed parts of the well should be insulated, as should the wall of the pipe or other container for some distance on either side of the well, if such insulation will not affect the temperature of the fluid being measured. The well should be constructed so that it has the smallest possible metallic connection, consistent with strength, with the wall of the pipe or other container in order to reduce heat flow along the well. The well should have sufficient surface area to enable it to absorb heat from the substance being measured as rapidly as it is lost from the exposed end.

Materials used in thermometer wells may be aluminum, brass, copper, glass, lead, nickel, plastic, rubber, stainless steel, or carbon steel, depending upon the fluid in which the well is immersed.

The response lag of a thermometer is nearly always increased to a considerable extent by the use of a thermal well. In many industrial applications the response lag may become an important factor.

**ACCURACY OF EXPANSION THERMOMETERS.** The accuracy of industrial liquid-in-glass and bimetallic thermometers is generally  $\pm 1.0\%$  of span. The accuracy of industrial transmitting thermometers is generally  $\pm 0.5\%$  of span. Thermometers of selected accuracy better than the figures given above can generally be obtained. The accuracy of any thermometer depends, among other factors, upon the conditions under which it is installed and used.

**THERMOCOUPLE PYROMETERS.** The thermocouple pyrometer consists essentially of a thermocouple of two different metals or alloys. The wires composing it are fused together at one end to form the measuring (hot) junction which is exposed to the temperature to be measured. The other ends are called the reference (cold) junction. The electromotive force, induced by the difference in temperature between the two ends, is proportional to the temperature difference and may be measured by an indicating instrument such as the millivoltmeter or potentiometer. These, together with leadwires connecting the thermocouple to the indicating instrument, complete the pyrometer. The thermocouple pyrometer is useful in measurement of temperatures between  $-300^\circ\text{F}$  and  $2800^\circ\text{F}$ .

Thermocouples in most common industrial use are given in Table 7. The useful range given in Table 7 is for a bare thermocouple of the largest size wire. If a smaller size wire is used, the upper limit of temperature is appreciably reduced. If a thermal well is used, the upper temperature limit is sometimes increased. Platinum thermocouples are nearly always used with a gastight thermal well.

Temperature-emf data for thermocouples are given in Tables 8, 9, 10, 11, and 12. Nearly all thermocouples except a very few types from certain manufacturers are made to match these calibrations.

FIG. 3. Thermometer well.

Table 7. Characteristics of Thermocouples

Thermocouple (Pos. Metal First)	Composition		Useful Temp. Range, $^\circ\text{F}$	Melt. Temp., $^\circ\text{F}$	Span, $^\circ\text{F}$ for 10 Mv	Average Accuracy, %
	Positive Metal	Negative Metal				
Chromel-alumel	90 Ni-9 Cr	97 Ni-3 Al	1000 to 2000	2570	440 at 1500	$\pm 3/4$
Iron-constantan	100 Fe	55 Cu-44 Ni	0 to 1400	2210	325 at 700	$\pm 1$
Copper-constantan	100 Cu	55 Cu-44 Ni	-300 to 600	1980	450 at 100	$\pm 3/4$
Chromel-constantan	90 Ni-9 Cr	55 Cu-44 Ni	1000 to 2000	2210		$\pm 3/4$
Pt 10% Rh-Platinum	90 Pt-10 Rh	100 Pt	0 to 2800	3220	1700 at 1400	$\pm 1/2$
Pt 13% Rh-Platinum	87 Pt-13 Rh	100 Pt	0 to 2800	3200	1515 at 1400	$\pm 1/2$

Special thermocouples have been used, mainly for the purpose of resisting corrosion and oxidation in particular applications. They are chromel versus KA2S, where KA2S is a metal similar to a stainless steel, iron versus alumel, and nickel versus nickel-molybdenum.

Platinum thermocouples are nearly always made from 24 B & S gage wire, 0.0201 in. in diameter. All other thermocouples are generally made of 8, 14, and 20 B & S gage wire.

Tube thermocouples are made of iron and constantan, with the iron in the form of a tube, the constantan wire running down the center of the tube. The purpose of this

construction is to improve the speed of response by avoiding use of a thermal well. Tube thermocouples are generally  $\frac{1}{8}$  in. outside diameter.

**Accuracy of Thermocouples.** The standard accuracy of thermocouples is given in Table 7. Special thermocouples selected for higher accuracy may be obtained at premium cost. These selected accuracies are: platinum couples— $\pm 1/4\%$ ; chromel-alumel couples— $\pm 3/8\%$ ; iron-constantan couples— $\pm 1/2\%$ . In addition, thermocouples can be obtained with an error curve giving its deviation from standard calibration; some may be supplied with a National Bureau of Standards certification.

\* Form of table by The Brown Instrument Company, Philadelphia, Pa. Data conform to Bureau of Standards specifications.

**Thermocouple Leadwire.** Thermocouples are calibrated for a certain reference-junction temperature. Any variation in this temperature will change the emf of the thermocouple and produce an error. Reference junction compensation is usually located at the millivoltmeter or potentiometer.

The hot junction of the thermocouple may be located several hundred feet from the instrument, and thermocouple leadwire is used to connect the thermocouple to the instrument. When cost is not prohibitive thermocouple leadwires are of the same materials as those composing the thermocouples.

Table 13 gives the thermocouple and leadwire combinations in common use. In Table 13 the first-named thermocouple wire is to be used with the first-named leadwire. Polarities of leadwires and thermocouples must be observed during installation.

**Thermal Wells.** In only a limited number of applications is it practical to expose the bare thermocouple to the fluid in which the temperature is being measured. Platinum thermocouples, especially, require careful protection against corrosion and contamination. Even with a thermal well, corrosion and oxidation may be so rapid that frequent replacement is necessary. The thermal well for a thermocouple is very similar in construction to the thermal well for a thermometer. Extra protection can be provided by using a secondary thermal well over the primary thermal well for the purpose of preventing sagging and making the assembly gastight.

Materials in common use for thermocouple protection are:

Metallic		Ceramic
Bronze	Iron, cast	Vycor
Monel	Iron, 28 chrome	Quartz
Steel	Nickel	Porcelain
Steel, calorized	Chromel	Firebrick
Iron, wrought	Chromax	Mullite
Iron, calorized	Nichrome	Sillimanite
Iron, 14 chrome	Inconel	Silica
Steel, stainless	Platinum	Silicon carbide

\* Form of table by The Brown Instrument Company, Philadelphia, Pa. Data conform to Bureau of Standards specifications.

The metals are listed in order of their temperature limit, bronze being the lowest, and platinum being the highest. The ceramics are also listed in order of their temperature limit.

A thermal well increases the response lag of the thermocouple, sometimes seriously. Careful attention should be given this matter during installation so that the most rapid heat transfer possible is effected. Radiation transfer of heat is important in nearly all thermocouple installations.

**Table 13. Thermocouples and Leadwires**

Iron-constantan	
Copper-constantan	
Platinum-Pt 10% Rh }	
Platinum-Pt 13% Rh }	

**Millivoltmeter.** The industrial millivoltmeter is a calibrated d-c galvanometer especially constructed for the measurement and indication of thermocouple emf. It is the simplest and least expensive of all instruments for use with thermocouples. The millivoltmeter is primarily an indicating instrument in which the pointer operates over a scale 5 or 6 in. long. Recording millivoltmeters are also in use but are becoming industrially less important.

Reference-junction temperature compensation is usually required in a millivoltmeter. Compensation is accomplished by a bimetallic strip which shifts the position of one of the hair springs controlling the millivoltmeter coil.

The accuracy of the millivoltmeter without a thermocouple is generally about  $\pm 1\%$  of span.

**Potentiometer.** The automatically balancing potentiometer incorporates a null potentiometer circuit for automatic indication of thermocouple emf. The instrument is available in several styles:

1. Indicating-linear scale, in which a pointer operates over a linear scale 6 to 12 in. long.
2. Indicating-concentric scale, in which a pointer operates over a circular scale of about 300 geometrical degrees. In some types a circular dial is made to rotate past a fixed index.
3. Recording-strip chart, in which a pen operates on a strip chart approximately 10 in. wide.
4. Recording-circular chart, in which a pen operates on a circular recording chart.

Reference-junction compensation is accomplished automatically in the potentiometer by a nickel coil in the potentiometer circuit. Since the potentiometer circuit requires a battery to produce a standard or comparison emf, means must be provided for standardizing this source. Standardization is accomplished by comparing the battery emf to the emf from a standard cell. It may be done manually or, in most instruments, automatically. Automatic reference-junction compensation is generally desirable for industrial use of the instrument. The accuracy of the automatically balancing potentiometer is generally better than  $\pm 0.25\%$  of span based on measurement of emf only. Potentiometers of selected accuracy can be obtained.

**RESISTANCE THERMOMETERS.** The resistance thermometer operates on the principle that the electrical resistance of a wire changes with temperature. Resistance of the thermometer bulb is measured by a Wheatstone bridge type instrument. The resistance thermometer is useful mainly in the measurement of temperatures between about  $-300^\circ\text{F}$  and  $1200^\circ\text{F}$ .

The resistance-thermometer bulb consists essentially of a coil of fine wire wound on or in a frame of insulating material. Materials in common use for resistance-thermometer bulbs are given in Table 14.

**Table 14. Characteristics of Resistance Bulbs**

Metal	Resistance, ohms at 32 F	Useful Temperature Range, °F	Melting Temperature, °F
Platinum	10 to 35 *	- 300 to 1200	3191
Copper	10	- 40 to 250	2161
Nickel	100 to 300	- 300 to 600	2646

\* May sometimes be as high as 125 ohms.

Resistance-thermometer bulbs are generally used with a thermal well except when the temperature measurement is being made in dry air. Platinum bulbs may be fitted with a well of porcelain, brass, or stainless steel which is sometimes sealed. The thermal well for the resistance thermometer closely resembles those for thermocouples and expansion thermometer bulbs.

The accuracy of resistance-thermometer bulbs is better than the accuracy for either thermocouples or expansion thermometers. Standard industrial resistance-thermometer bulbs are generally accurate to  $\pm 0.25\%$ , varying slightly for different temperature ranges. Resistance bulbs may be obtained of selected accuracy better than that given above.

Leadwire compensation for temperature variations is accomplished usually by the Siemens three-lead method for connecting the resistance bulb into the Wheatstone bridge circuit. Ordinary copper wires may be used to connect the resistance-thermometer bulb to the instrument. The distance between resistance-thermometer bulb and instrument may be almost any reasonable value.

The null-bridge resistance thermometer closely resembles physically the automatically balancing potentiometer but includes a Wheatstone bridge or similar bridge arranged for automatic balancing. However, a standard cell, standardization, and reference junction compensation are not required. The potential supply, either alternating or direct current, should be reasonably constant. The instrument may be obtained in either indicating or recording styles, as for the potentiometer. The accuracy of the null-bridge resistance thermometer is generally better than  $\pm 0.25\%$  of span.

The deflectional resistance thermometer uses a circuit similar to the d-c Wheatstone bridge, except that there is no adjustable resistor for balancing the bridge. The instrument, a type of indicating millivoltmeter, is generally used for indicating such temperatures as are encountered in building installations and in air conditioning.

**RADIATION METHODS.** The intensity of the radiant energy emitted by a body is an indication of the temperature of that body. The intensity of radiation depends both upon the temperature of the body and upon the material composing it. If two similar hot bodies are at the same temperature, and the first is found to radiate energy at twice the rate of the second, the first is said to have twice the emissive power of the second. A material with the highest possible emissivity is known as a *black body*. Black-body conditions are closely approached by a uniformly heated hollow enclosure or by a small opening in a heated body. The numerical value 1.0 is usually applied to the emissivity of a black body, and all nonblack-body materials have an emissivity of less than 1.0 (see also Radiation, Section 3).

The radiation methods of measuring temperature are represented by the radiation pyrometer, the optical pyrometer, and the photoelectric pyrometer. The useful temperature ranges of these instruments are indicated in Table 15. Theoretically there is no upper temperature limit for radiation methods of measurement, but the values in Table 15 are those occurring in industrial use.

Table 15. Useful Temperature Ranges of Radiation Methods

Pyrometer Type	Lower Limit, °F	Upper Limit, °F
Radiation	200	3500
Optical	1000	5000
Photoelectric	1500	3000

The radiation pyrometer uses emission from a radiant body focused upon the hot junction of a small thermocouple in the pyrometer; the temperature to which this junction rises is approximately proportional to the rate at which the energy falls upon it. According to the Stefan-Boltzmann law, this temperature is proportional to the fourth power of the absolute temperature of the source of radiation. The electromotive force generated by this temperature rise is measured by a potentiometer, as in the thermocouple pyrometer, calibrated to form the relation between the emf and the temperature of the radiant body.

The effects which must be considered in the use of the radiation pyrometer are the distance effect, the emissivity effect, the absorbing media effect, and the reference-junction temperature effect.

Readings generally are independent of the distance of the instrument from the source of radiation, provided that the image more than covers the disk or black spot in the receiver. The radiation pyrometer tends to give a reading lower than the true reading as the sighting distance is increased or the size of the radiant body is decreased.

Radiation pyrometers are calibrated to read correctly when sighted on a black body. Most furnaces approximate black-body conditions. A material in a furnace at furnace temperature cannot be distinguished from the surroundings and may be considered a black body. If the coefficient of actual emissivity of the material is 0.45 its reflection

coefficient will be 0.55, and the total emissivity of the body will be 1, or that of a black body. That is, 55% of the energy radiated from the body will be reflected from the surrounding walls which are at the same temperature. If, however, the material is removed from a furnace it will then emit only 45% of the radiant energy of a black body at the same temperature, and the radiation pyrometer will therefore read too low.

Materials in the open should have a correction applied to the observed temperature to convert it to the true temperature. Table 16 shows a corresponding true and apparent temperature observed with a radiation pyrometer sighted on materials in the open.

**Table 16. True Temperature Corresponding to Apparent Temperature Measured by Radiation Pyrometers When Sighted upon Materials in the Open**

2190	3180	....	....	2300	2290

Such media as lenses, glass windows, smoke, dirt, and gases between the source and the radiation receiver cause the instrument to read low. Hot gases, flame, and high-temperature carbon particles may cause the instrument to read high. If such conditions prevail it may be necessary to use a target tube with the radiation receiver. The target tube is a closed-end tube of metal or ceramic installed in the side of a furnace. The radiation receiver is sighted into the tube where black-body conditions are closely approached. Target tube materials are silicon carbide, sillimanite, inconel, nickel, chrome nickel, wrought iron, and steel.

The reference junction of the thermocouple is generally located in the radiation receiver. For this reason the housing of the radiation receiver should be maintained at substantially constant temperature. In some types automatic reference-junction compensation is supplied.

The accuracy of a radiation pyrometer calibrated under black-body conditions is usually better than  $\pm 0.5\%$ . The accuracy under actual use depends considerably upon the details of the installation. The response of a radiation receiver is extremely fast and is one of the important advantages of this means of temperature measurement.

The industrial millivoltmeter or automatically balanced potentiometer instrument is used to measure the emf developed by the radiation receiver. The radiation receiver may be connected to the instrument with ordinary copper leadwire because both the hot and reference junctions of the thermocouple are located in the radiation receiving unit.

**Optical pyrometers** measure the energy radiated from incandescent bodies and utilize only that portion of the total energy in a narrow band near the visible red. In most types radiation from the target surface is focused by the lens onto a screen. The screen is viewed through a red filter glass so that only wavelengths of about 0.65 micron are seen. For comparison the radiation from a calibrated tungsten lamp is focused on a screen and also viewed through a red filter glass. The two screens are then compared by eye. There are two methods for varying the brightness of the screen images. First, the current through the standard lamp may be adjusted and the brightness of the standard screen matched against the brightness of the screen illuminated by radiation from the target surface. The current to the standard lamp may be measured and a scale calibrated in terms of temperature. Second, the intensity of the radiation from the target surface may be varied by using wedges of absorbing material. The wedge is moved to match the images on the two screens and a scale is arranged for indication of temperature.

Optical pyrometers are calibrated to read correctly when sighted on a black body. Bodies heated in a furnace approximate black-body conditions, and the temperature measurement is not seriously in error. Such error as exists will give a reading higher than the true reading if the furnace walls are brighter than the target surface, and lower than

the true reading if the target surface is brighter than the walls. The pyrometer should be sighted into a deep wedge-shaped cavity or hole in the target surface.

The optical pyrometer sighted on glowing material in the open reads too low. Table 17 gives the corrections for various industrial materials when measured by optical pyrometers. The optical pyrometer will not give satisfactory readings when sighted through flames or smoke.

The accuracy of most optical pyrometers is very high; temperatures can be determined to within  $\pm 5.0$  F. Optical pyrometers are manually operated instruments.

**Photoelectric pyrometers** are employed mainly where a simple, fast method of temperature measurement is desired. Some types use a photovoltaic cell and a millivoltmeter or potentiometer to measure the generated emf. Other types employ a photoemissive cell with an amplifying circuit, together with a comparison system based on a standard lamp as in an optical pyrometer. For further detail, consult one of the references at the end of this chapter (p. 18-22), particularly Rhodes or Weber.

## 2. METHODS OF MEASURING PRESSURE

The unit of pressure for nearly all engineering work is pounds per square inch.

There are three scales used for expression of pressure units: absolute pressure, gage pressure, and vacuum. Gage pressure is measured as the pressure above the atmospheric pressure existing at the time and place of measurement. Atmospheric or barometric pressure referred to standard conditions can be found in Table 18 in the vertical column under "atm." Shown also are pressure-conversion factors.

Absolute pressure is related to gage pressure and vacuum by

$$P_a = P_g + B = B - V$$

where  $P_a$  = absolute pressure,  $P_g$  = gage pressure,  $V$  = vacuum,  $B$  = barometric pressure, all expressed in the same units.

**Differential pressure** is a difference in pressure and is therefore independent of the particular scale used. Low absolute pressures (high vacuums) are generally expressed in microns, that is, in microns of mercury column where a micron is one-thousandth of a millimeter.

Measurement of pressure in terms of water or mercury column height must contain a specification of temperature, either implicitly or explicitly, since the height of a liquid column depends upon the density or specific gravity of the liquid which changes with temperature. The corrections are small as is shown in Table 19.

**LIQUID MANOMETERS.** The common types of liquid manometers are the U-tube manometer, the well manometer, the inclined tube manometer, and the ring manometer, all shown in Fig. 4. All manometers with one leg open to atmosphere measure gage pressure. For a U-tube manometer,

$$P_a \text{ (psia)} = \frac{hD}{1728} + B \text{ (psia)}$$

where  $h$  = the difference in height of columns, inches;  $D$  = density of manometer liquid, pounds per cubic foot at ambient temperature;  $B$  = barometric pressure. In a well-type manometer, one leg is enlarged so that the change of liquid level in the well or cistern is so small as to be negligible in all except precision measurements. In this case the same relation as above exists between head and pressure.

Fig. 4. Liquid manometers.

The inclined-tube manometer is used for very low pressures or vacuums. They are most commonly used as draft gages.

The ring-type manometer is constructed as shown in Fig. 4 so that the center of gravity of the system is below the pivot. When a pressure difference is applied the ring rotates until the moment caused by the additional liquid on one side equals the moment caused by the center of gravity on the other side.

Any of the manometers may be used for the measurement of gage pressure, vacuum, or differential pressure by suitable arrangement of the connections on the two sides of the manometer. Liquid manometers can be used up to about 300 psig pressure, depending upon the strength and sealing of the gage glasses.

The most common manometer liquids are water and mercury. Infrequently alcohol, kerosene, benzol, and oils of various composition are used.

**INDICATING-RECORDING MANOMETERS.** A mercury manometer may be made indicating or recording by employing a float in one leg of the manometer as shown in Fig. 5. The mechanical connection to the float is brought through the wall of the float chamber by means of a pressure-tight shaft. The change of level of mercury in the float chamber is generally about one-half inch. By changing the area of the leg not containing the float, ranges of differential pressure from 0 to 20 in. of water up to several hundred inches of water may be obtained. Recording manometers are made to withstand up to 2500 psig and sometimes even higher pressures. The instrument may be used for low gage pressures, vacuums, and low differential pressures. Eccentric-indicating styles and circular-chart recording styles are obtainable. Recording manometers of this kind are most commonly used for orifice flowmeters, and as such there are many varieties of mechanical and electrical forms.

Fig. 5. Indicating manometer.

Fig. 6. Bell gage.

**BELL GAGES.** Bell-type gage for gage pressure, differential pressure, and vacuum measurements is shown in Fig. 6. The difference in pressures acting against the area of the bells causes the beam to deflect from its equilibrium position, and the instrument may be calibrated in pressure units. The function of the liquid is merely to seal the bells. Pressures and vacuums down to a fraction of an inch of water may be measured, but obviously the instrument is limited to low total pressures. Eccentric-indicating and circular-chart recording styles are available.

**DIAPHRAGM GAGES.** Gages for the measurement of draft pressures (vacuum or gage) employ a flexible diaphragm of oil-treated leather. The pressure acts against the effective area of a diaphragm and causes a spring to deflect an amount proportional to pressure. The range of such gages is usually in inches of water, and they are generally eccentric indicating. For higher pressures, flexible metallic diaphragms are sometimes used.

**RECORDING ANEROID METER.** For the measurement of low differential pressures, as in an orifice flowmeter, a bellows of large area may be used, one pressure being placed on the outside of the bellows and the other on the inside of the bellows. The differential pressure acting against the effective area of the bellows causes a spring to deflect an amount proportional to the differential pressure. The bellows is sealed in a cast-iron or steel housing, and the motion of the bellows is transmitted through the housing by a sealed torque tube. Indicating and circular-chart recording styles are available.

**BELLOWS GAGES.** For moderately low pressures of 1 to 50 psig, a bellows-type element may be used. The bellows may be of brass, phosphor bronze, beryllium copper, stainless steel, or monel. The range of the instrument is determined by the effective area of the bellows and the spring gradient. Eccentric-indicating, concentric-indicating, and circular-chart recording styles may be obtained.

**BOURDON-TUBE GAGES.** For pressures of 20 to 10,000 psig, a bourdon-tube element, a spiral element, or a helix element is used. A spiral is a bourdon tube of more than one turn wound in one plane at varying diameter. A helix is a bourdon tube of more than one turn wound at a common diameter. The bourdon-tube element may be of phosphor bronze, beryllium copper, or steel. Pressure gages with concentric or eccentric indicating dials may be obtained in a large variety of styles and in dial sizes of 2 in. up to 14 in. in diameter. They are in very common industrial use since they are inexpensive in moderate sizes. Circular-chart recording gages may also be obtained.

**ABSOLUTE-PRESSURE GAGES.** An absolute-pressure gage is constructed by employing a bellows-type gage with a barometric compensator as shown in Fig. 7. The

Fig. 7. Absolute-pressure gage.

upper bellows is evacuated and sealed while the unknown pressure is applied to the lower bellows. Changes in barometric pressure are compensated by the action of the upper bellows. Obviously barometric compensation is important only in measurement of pressures up to about 300 psig. The instrument is usually circular-chart recording.

### 3. METHODS OF MEASURING HEAD

Head or liquid level is expressed in distance units, such as inches, feet, or meters, above a given reference plane. Sometimes, however, liquid level is expressed in volume units,

Fig. 8. Free-float liquid-level gage.

such as cubic feet or gallons, or even in terms of weight units, such as pounds. In order to make these measurements explicit all necessary data, such as temperature, specific gravity, and static pressure, should be specified.

**FREE-FLOAT LIQUID-LEVEL GAGE.** The free-float type of gage is shown in Fig. 8. The float is free to follow the surface

Fig. 9. Displacement-float liquid-level gage.

of the liquid, the motion of the float being brought out of the chamber through a pressure-tight shaft. The range of an instrument of this kind is limited to a few inches change in liquid level. The static pressure above the liquid may be as high as 2500 psig. Other types of free-float liquid-level gages are arranged with a chain or a tape so that changes of liquid level up to 20 or 30 ft may be measured. This latter type is more suitable for open vessels. Free-float liquid-level gages may be obtained in indicating and circular-chart recording styles.

#### DISPLACEMENT-FLOAT LIQUID-LEVEL GAGE.

This type is shown in Fig. 9. The float is restrained by the springs attached to the arm, or by similar means, so that the buoyancy of the float causes the float arm to deflect as the liquid head at the float changes. This type is not restricted to small changes in level since the float may be several feet in length.

Fig. 10. A manometer used for measuring liquid level.

**MANOMETER-TYPE LIQUID-LEVEL GAGE.** In a closed vessel under pressure it is sometimes advantageous to use an indicating or recording manometer. This method is indicated in Fig. 10. The manometer may be constructed for as low as 20 in. of water up to

Fig. 11. Pressure-type liquid-level gage.

several hundred inches of water change in head. In installing this kind of liquid-level gage it is important that careful consideration be given the effect of the various liquids in the legs of the manometer. Both mechanical and electrical types may be used.

**STATIC-PRESSURE-TYPE LIQUID-LEVEL GAGE.** Where the changes of liquid level are appreciable in extent it may be possible to use an ordinary pressure gage for the measurement of the liquid level as shown in Fig. 11. Here is shown a bellows pressure gage employing a diaphragm seal for the purpose of excluding the measured liquid from the pressure-gage system. Another method that is often employed is to use an air-purge system which maintains a slight positive pressure in the pressure-gage line, the excess air being allowed to bubble out of the gage line into the vessel.

### 4. METHODS OF MEASURING FLUID FLOW

There are four methods in common industrial use for the measurement of fluid flow in closed pipes. They are exemplified by quantity meters, velocity meters, head meters, and

area meters. (For the measurement of liquid flow in open channels, see Hydraulics, Section 5, Art. 8.)

Units of fluid flow may be expressed in almost any volume or weight dimensions. However, total quantity of liquids is usually given in gallons, and total quantity of gases is usually given in cubic feet. Flow rate of liquids is usually given in gallons per minute (abbreviated gpm), and flow rate of gases is usually given in cubic feet per hour (abbreviated cfh). These quantities and flow rates are usually given at standard conditions such as 60 F and 30 in. Hg instead of operating conditions.

**QUANTITY METERS.** In quantity meters the fluid, gas, or liquid passes in discrete quantities, each quantity of identical volume. There are many types of quantity meters; among them are the reciprocating piston, the oscillating piston, the nutating disk, and the geared impeller types for liquids, and the geared impeller, bellows, and sealed drum types for gases.

Quantity meters make use of a counter which can be calibrated to give the total quantity in terms of either volume or weight passed at a given point.

Quantity meters for liquids will handle 0.05 up to 700 gpm. They may be operated under static pressures up to 1000 psig. Their accuracy is very good even at low flows. The piston types usually have an accuracy within about 0.2%. The accuracy of other types is usually about 0.5 to 1.0%. Quantity meters for gases will handle up to 50,000 cfh at a pressure of 500 psig. Their accuracy is usually one-half of 1%.

The advantages of a quantity meter are that it is accurate and is not seriously affected by temperature, pressure, and density. The disadvantages are that they are usually expensive in large sizes and are not suitable for liquids containing solid matter.

**VELOCITY METERS.** In velocity meters a rotor is continuously turned by the motion of the flow stream. In one type a propeller screw, smaller in diameter than the pipe, is rotated by the impact velocity of the stream. In another type a turbine rotor is made to turn by the force on the blades caused by the flowing stream. The velocity meter has a greater flow capacity than the quantity meter, causes less pressure loss, and may be used for the flow of abrasive materials.

The accuracy of velocity meters is subject to the influence of density, viscosity, and temperature. They are not as accurate at low flows as quantity meters.

**MEASUREMENT OF FLOW BY HEAD METERS.** In head meters the flow of liquid across a resistance of constant area causes a difference in pressure to exist. An orifice plate, flow nozzle, or venturi tube is used for the resistance, and the differential pressure may be measured by any of the manometers or differential pressure gauges discussed previously.

Orifice arrangements used in commercial practice are shown in Fig. 12. The thin-plate orifice is the simplest and the least expensive of any of the primary elements. It may be obtained in many different materials and in sizes for 2 to 14 in. diameter pipe. It causes the largest pressure loss of the three primary elements.

Orifice plates may be installed with vena contracta taps, flange taps, or pipe taps (see Section 1, Art. 7). Vena contracta taps are installed so that the downstream tap is located at the point of minimum static pressure. This arrangement results in the maximum pressure differential for a given flow but also requires that the taps be moved if the orifice size is changed. Flange taps are installed in a separate flange with the taps about one inch upstream and downstream from the orifice plate. This arrangement is the simplest and easiest to install. Pipe taps are installed sufficiently far from the orifice so that they measure the permanent pressure loss. This arrangement results in the smallest pressure differential for a given flow and is not as commonly used.

The theory of fluid flow is discussed in Sections 1 (Air), 3 (Heat, etc.), 4 (Steam, etc.) and 5 (Hydrodynamics, etc.) of this book. The following equations may be used for the flow of fluids (liquid or gas) through an orifice. The equations are based on the use of any kind of mercury manometer for the measurement of the differential pressure, and the manometer is assumed to be at 80 F ambient temperature. The equations will allow a computation correct to about 1%. In the equation for gases the expansion and compressibility effects are neglected, and the gas is assumed to be dry. The flow rate is given in terms of quantity at 60 F and, for a gas, at 30 in. Hg.

FIG. 12. Orifice arrangements.

$$\left. \begin{aligned} W &= 1270\beta^2 K D^2 \sqrt{\frac{H}{v}} \\ N &= \frac{5.05W}{\mu\beta D} \end{aligned} \right\} \text{Steam}$$

 N &= \frac{3160xQ}{\mu\beta D}
 \end{aligned}
 \left. \vphantom{\begin{aligned} Q &= 5.67\beta^2 KD^2 \sqrt{zH(13.53 - y)} \\ N &= \frac{3160xQ}{\mu\beta D} \end{aligned}} \right\} \text{Liquids}$$

$$\begin{aligned}
 V &= 7700\beta^2 KD^2 \sqrt{\frac{hP}{Tx}} \\
 N &= \frac{13.64PxV}{T\mu\beta D}
 \end{aligned}
 \left. \vphantom{\begin{aligned} V &= 7700\beta^2 KD^2 \sqrt{\frac{hP}{Tx}} \\ N &= \frac{13.64PxV}{T\mu\beta D} \end{aligned}} \right\} \text{Gases}$$

$$\beta = \frac{d}{D} \text{ diameter ratio}$$

where  $\beta$  = diameter ratio;  $d$  = orifice internal diameter, inches;  $D$  = pipe internal diameter, inches;  $h$  = orifice differential pressure, inches of water;  $H$  = orifice differential pressure, inches of mercury;  $K$  = orifice flow coefficient (Tables 20 and 21);  $\mu$  = fluid viscosity at flowing conditions, centipoise;  $N$  = Reynolds' number;  $P$  = static pressure at flowing conditions, psia;  $Q$  = quantity flow rate, gallons per minute;  $\rho$  = fluid density at flowing conditions, pounds per cubic foot;  $T$  = fluid temperature at flowing conditions,  $^{\circ}\text{R}$ ;  $v$  = specific volume at flowing conditions, cubic feet per pound;  $V$  = volume flow rate, cubic feet per hour;  $W$  = weight flow rate, pounds per hour;  $x$  = fluid specific gravity at flowing conditions;  $y$  = fluid specific gravity at 80 F;  $z$  = reciprocal of fluid specific gravity at 60 F.

To determine pressure differential when orifice size and flow rate are known: (1) Compute  $\beta$ . (2) Compute  $N$ . (3) Find  $K$  in Tables 20 and 21 (interpolate if necessary). (4) Compute pressure differential ( $H$  or  $h$ ).

To determine flow rate when orifice size and pressure differential are known: (1) Compute  $\beta$ . (2) Assume a value for flow rate ( $W$ ,  $Q$ , or  $V$ ). (3) Compute  $N$ . (4) Find  $K$  in Tables 20 and 21 (interpolate if necessary). (5) Repeat steps 2 to 4 if necessary.

To determine orifice size when flow rate and pressure differential are known: (1) Assume a value for orifice diameter ( $d$ ). (2) Compute  $\beta$ . (3) Compute  $N$ . (4) Find  $K$  in Tables 20 and 21 (interpolate if necessary). (5) Compute flow rate. (6) Repeat steps 2 to 5 if necessary.

For further detail consult Gess, Spink, *Flow Measurement*, ASME, 1940, or *Fluid Meters, Theory and Application*, Part 1, ASME, 1937.

An orifice plate must be carefully installed in a straight run of pipe with no fittings or obstructions less than about 20 pipe diameters upstream and about 5 pipe diameters downstream. Straightening vanes may be required in some cases. Consult references for specific details.

A flow nozzle or venturi tube (Fig. 13) may also be used with a head meter, although they are not as common. The pressure loss with these elements is not as great as with the orifice plate. They are more expensive than an orifice plate, and fewer data are available

on their coefficients. (See *Fluid Meters, Theory and Application*, p. 105, for flow nozzles and p. 99 for venturi tubes.)

A pitot tube (Fig. 14) is also used with a head meter. It is not as accurate as an orifice or venturi, but its use becomes necessary when flow measurements are made in large pipes and ducts. It has the advantage that velocity traverses of the pipe or duct can be made. (See *Fluid Meters, Theory and Application*, p. 69.)

Fig. 13. Flow nozzle and venturi tube elements.

Fig. 14. Pitot-tube element.

The pressure connections between any of the primary elements and the manometer instrument must be considered in the calibration and use of a head meter. Often the manometer legs are filled with a liquid of different density from the manometer liquid, and liquid seals may be necessary to keep corrosive fluids out of the manometer. Such factors affect the calibration of the instrument. The manometer piping must be installed in accordance with standard practices.

In gas-flow measurement the flow rate measured by the head meter is dependent upon the static pressure of the gas. If this static pressure varies it must be measured independently so that flow readings may be compensated in accordance with the formula for flow of gases. Some head meters may be obtained with an additional static pressure-measuring element connected to them in such a way as to compensate for variations in gas pressure.

The scale calibration of a head meter has a square-root characteristic unless the manom-

eter has a special means for extracting the square root to produce a semi-linear scale. The instrument may be either indicating or circular-chart recording. With one of the primary elements discussed above, flows of almost any reasonable values may be measured. The accuracy of a head meter is usually about  $\pm 0.5\%$  of span above 30 or 40% of scale. At low readings on the scale the accuracy of a head meter cannot be depended upon although it will usually approach  $\pm 1\%$ .

**AREA METERS (ROTAMETER).** In area meters a variation of area is presented to the flowing stream under constant differential pressure. The most common form is the rotameter shown in Fig. 15.

Fig. 15. Area meter or rotameter.

The float is supported in the flow stream by the pressure difference across the float, the greatest pressure being on the bottom of the float, and by the impact pressure on the bottom of the float. These forces upward must be balanced by the downward force of float weight. A rotameter is therefore installed in a vertical position. The float is usually carried in the center of a tapered glass tube, and the float may or may not be guided. The glass tube can be calibrated directly with a scale reading in terms of flow rate.

By suitable changes in float design the rotameter calibration may be compensated for changes in density and changes in viscosity of flowing fluid. The location of a rotameter close to fittings or obstructions in the line does not influence its accuracy as much as this location would influence the head meter.

The advantages of a rotameter are that they can handle many corrosive fluids, the scale calibration is nearly linear, and they are reasonably accurate at low flows. On the other hand, rotameters are not as rugged as head meters and quantity meters and they are expensive in large sizes.

For automatic indicating or recording of fluid flow the displacement of the float may be transmitted by pneumatic, electrical, or magnetic means to an indicating or circular-chart recording instrument.

The accuracy of rotameters is generally  $\pm 0.5\%$  above 10% of maximum flow and with special calibration may be better than that, particularly at low flows.

**INTEGRATION OF FLOW RATE.** A head meter records the rate of flow in such units as gallons per minute. To obtain the total quantity it is necessary to integrate the flow rate over a period of time. This may be done manually, by a planimeter, or by an automatic integrator.

Most recording head meters use circular charts, which may be integrated manually by selecting small intervals of time, such as 15 minutes, and multiplying the average flow rate by the time period. For gas flow it is necessary to correct for variations in pressure by using the gas-flow formula.

A planimeter designed especially for use with circular charts of square-root characteristic is available from the manufacturers of recording meters.

Automatic integration may be obtained for nearly all recording head meters and area meters. Mechanical types of integrators employ the principle of the disk and wheel and are driven in a periodic manner from a small synchronous motor. For gas flow with varying static pressure, two integrators are used. On some head meters electrical integrators are used.

Integration of flow rate cannot generally be made more accurate than  $\pm 0.5\%$  with either a planimeter or an automatic integrator. Over long periods of time, such as a week or month, the error of integration is cumulative, and accurate check of total quantity is difficult to establish.

## AUTOMATIC CONTROL

An automatic controller, sometimes called a regulator, is a mechanism which measures the value of a variable quantity or condition and operates to correct or limit deviation of the measured value from a selected reference. Thus the purpose of an automatic controller, in addition to the controlling function, is to perform a measurement. Almost any of the instruments or meters discussed in the previous section may be used as an automatic controller by combining a controlling means with its measuring means.

An automatic controller, together with the process which it controls, constitutes a closed loop of action and reaction as shown in Fig. 1. The automatic controller measures,

with a primary element, some variable quantity or condition associated with the balance or performance of the process. This quantity is called the controlled variable. The controller then moves or operates a final element in response to a function of the deviation. The final element determines the value of a manipulated variable, which in turn operates through the process to alter the value of the controlled variable. The effect of the manipulated variable on the controlled variable must be to oppose the change or trend already existing at the controlled variable.

Fig. 1. Closed loop of automatic control.

Process disturbances, represented by the arrows in Fig. 1, cause the controlled variable to deviate from the desired value. It is the purpose of the automatic controller to eliminate as much as possible the effect of these disturbances.

The action and reaction in the closed loop are never instantaneous; these operations take time to occur. The main problem in automatic control is to select an automatic controller which will provide satisfactory performance in spite of these delays or lags.

## 5. ACTIONS OF AUTOMATIC CONTROLLERS

Every automatic controller has a specific method by which it accomplishes the purpose of automatic control. This is called the **action of control**.

**TWO-POSITION ACTION** is an action in which the final element is moved from one of two fixed positions to the other. This controller action is often called "on-off" or "open and shut." It is the simplest automatic-control action and is probably the most widely used. The simple thermostat which turns on a heater when the temperature is low and turns off a heater when the temperature is high is an example of this action.

**TWO-POSITION DIFFERENTIAL ACTION** is an action in which a final element is moved from one of two fixed positions to the other when the controlled variable reaches a predetermined value from one direction, and subsequently is moved to the other position only after the variable has passed in the opposite direction through a range of values to a second predetermined value. The differential gap is therefore similar to a hysteresis in the controller action, except that the differential is usually added intentionally to the controller action.

**SINGLE-SPEED FLOATING ACTION** is an action in which the final element is moved at a single rate. With these controllers the final element is in the act of gradually closing or gradually opening, and floats in a partly open position. A single-speed floating action does not recognize rate or magnitude of deviation but acts only upon the elapsed time of the deviation. In order to stabilize the action of the controller a neutral zone is often used so that no corrective action of the controller results when the controlled variable is within this zone.

**PROPORTIONAL-SPEED FLOATING ACTION** is an action in which there is a continuous linear relationship between the value of the controlled variable and rate of motion of the final element. The equation for this controller is

$$-\frac{dP}{dt} = fD$$

where  $P$  = position of final element,  $f$  = floating rate,  $D$  = deviation of measured variable,  $t$  = time.

Another form of the equation is:

$$-P = f \int D dt + K$$

where  $K$  is a constant of integration.

As these equations show, the controller recognizes not only *elapsed time* of deviation but also *magnitude* of deviation. A floating rate adjustment ( $f$ ) is arranged so that the proportionality can be made between rate of change of final element position and deviation.

**PROPORTIONAL ACTION** is an action in which there is a continuous linear relationship between value of the controlled variable and position of the final element. The equation for this controller is

$$-P = \frac{1}{s} D + K$$

where  $s$  is the proportional band and  $K$  is a constant. Thus a proportional controller operates the final element in accordance with the magnitude only of the deviation. The proportional band adjustment ( $s$ ) is similar to an amplification ratio which merely relates the motion of the final element to the magnitude of the controlled variable.

**PROPORTIONAL PLUS RATE ACTION** is an action in which a rate action is added to the proportional action. In rate action there is a continuous linear relationship between the rate of change of the controlled variable and the position of the final element. The equation for this controller is

$$-P = \frac{1}{s} D + \frac{q}{s} \frac{dD}{dt} + K$$

where  $q$  is the rate time. This action is often called a proportional plus derivative or a proportional plus rate-response action. The rate-time adjustment ( $q$ ) adjusts the relationship between the rate of change of the controlled variable and the position of the final control element. In most controllers of this kind an adjustment of the proportional band ( $s$ ) affects the proportional and the rate actions simultaneously.

**PROPORTIONAL PLUS RESET ACTION** is an action in which the proportional and proportional-speed floating actions are added. The equation for this action is

$$-P = \frac{r}{s} \int D dt + \frac{1}{s} D + K$$

where  $r$  is the reset rate. This is sometimes called a proportional plus integral action. The reset rate ( $r$ ) determines the magnitude of the proportional-speed floating action. With most controllers of this kind the proportional band adjustment ( $s$ ) affects both responses equally.

**PROPORTIONAL PLUS RESET PLUS RATE ACTION** is an action in which the proportional speed floating, proportional, and rate actions are added. The equation for this controller is

$$-P = \frac{r}{s} \int D dt + \frac{1}{s} D + \frac{q}{s} \frac{dD}{dt} + K$$

## 6. TYPES OF CONTROLLERS

The **self-contained controller** or regulator used in temperature control and pressure control is the most common type.

Fig. 2. Pressure regulator.

These types are usually called the pressure regulator (Fig. 2) and the thermostatic valve (Fig. 3). The self-contained regulator is recognized by the fact that it requires no auxiliary supply of power since it operates entirely from the power developed in its measuring means. These devices, widely used in industry, are available in a great variety of sizes and operating ranges, all of them employing proportional control action.

Pressure regulators are installed directly in the line through which a fluid, such as water, air, or steam, is flowing. They will operate to maintain pressures from a few inches of water up to thousands of psig at moderate rates of flow. Most simple pressure regulators do not operate well at very small flow rates far under their average capacity.

Thermostatic valves are installed directly in a steam

or hot-water line leading to the tank or vessel in which the temperature is controlled. They are available in ranges for refrigeration service and for temperatures up to about 300 F. A thermostatic valve usually has a solid-filled liquid thermal system with a bulb and capillary.

**PNEUMATIC CONTROLLERS** are in wide use because of their simplicity, speed, and precision of operation. The pneumatic on-off controller is shown in Fig. 4. The bellows, as in a pressure gage, operates a light metal vane positioned close to the open end of a nozzle. The nozzle is supplied with air through a restriction. When the vane covers and uncovers the nozzle, the back pressure at the nozzle is changed, and this pressure may be used to operate a diaphragm control valve or other final control element.

The **proportional controller** (Fig. 5) operates on the same principles except that a feedback bellows is used to increase the stability of the pneumatic system. Other pneumatic controllers include reset action and rate action and their various combinations.

Pneumatic controllers require an air supply of about 15 to 25 psig. This air supply

Fig. 3. Thermostatic valve.

Fig. 4. Pneumatic two-position controller.

Fig. 5. Pneumatic proportional controller.

should be clean and dry and should be available at about 100 to 125 psig. An individual pressure regulator and air filter is ordinarily used in the air supply to each controller. The output range of most pneumatic controllers is about 0 to 20 psig. Each pneumatic control requires about 0.5 cu ft of free air per min or less.

Fig. 6. Pneumatic diaphragm motor.

**Sensitivity and accuracy** of a pneumatic proportional controller are extremely high, and the equivalent of several thousand positions is available. For this reason they are more often used for proportional control (and various combination actions) than any other kind of controller.

**Diaphragm motors** of the type illustrated in Fig. 6 are most commonly used with pneumatic controllers. These motors may be used with plug valves, rotary valves, butterfly valves, dampers, and louvers. Diaphragm motors may provide up to about 2000 lb force at 2 or 3 in. stroke. The diaphragm motor very often is supplied with a positioning device in order to increase its power, speed, and sensitivity. Pneumatic positioning devices usually operate on about a 2 to 14 psig range from the pneumatic controller. The positioning device usually requires a separate filtered and regulated air supply from 20 to 100 psig; its air consumption is roughly about 1 to 2 cu ft of free air per min.

**ELECTRIC CONTROLLERS** of the two-position type are probably the most common type of controller in industrial service. There are essentially three methods of operation: the vane-type controller, the contact-type controller, and the proportional-type controller.

The **vane-type controller** is shown in Fig. 7. The bellows, as in a transmitting expansion

thermometer or in a pressure gage, positions a light metal vane in or out of the space between two small coils. The change in mutual inductance between the coils controls

FIG. 7. Vane-type electric controller.

mercury switch contacts operated directly by the measuring means, as in a home thermostat, or operated indirectly by a small auxiliary motor, as in a millivoltmeter controller. These controllers also may be obtained with a large variety of contact actions.

Solenoid valves are often used with vane-type and contact-type controllers, usually, however, in small sizes of single-seated plug valves. Electric-motor valves employ a motor of appropriate size for operating plug valves, butterfly valves, rotary valves, and dampers. Electric-motor valves are arranged so that they may be used as two-position or on-off controllers with a valve travel speed of 15, 30, and 60 sec.

Some are constructed so that they may be used as single-speed floating controllers.

Vane-type and contact-type controllers are often used for on-off control of small electric furnaces and electric heaters; sometimes power relays are used to handle heavier electric currents.

FIG. 9. Hydraulic proportional-speed floating controller.

an oscillator amplifier in such a manner that when the vane is between the coils a relay is closed and when the vane is out of the coils a relay is opened. (The operation may be reversed.) The relay can then be used to operate a solenoid valve or an electric-motor valve. Vane control may be used with almost any of the measuring instruments discussed in the first section, and they may be obtained with a large variety of relay actions.

Contact-type controllers are made with open metal-to-metal contacts or

FIG. 8. Electric proportional controller.

The electric proportional controller is also widely used, generally with the potentiometer-type instrument. Their operation is indicated in Fig. 8. Two slidewires, one at the instrument and the other on the motor valve, are employed in a bridge-type circuit. The potentiometer measuring means positions the contactor along the slidewire, producing an unbalance in the bridge. This unbalance is amplified and applied, usually by relays, to an electric-motor valve. The electric-motor valve then moves to a new position corresponding to the position of the opposing slidewire and rebalances the bridge. Reset action and rate action are available in various combinations.

The sensitivity and accuracy of an electric proportional controller can be expressed as the equivalent of about 200 positions at the motor valve.

Electric controllers of the industrial type usually operate from a 110-volt a-c 50- to 60-cycle power supply; each controller may require up to 3 or 4 amp. Controllers operating on a 25-cycle a-c or on a d-c power supply are sometimes available.

Electric proportional controllers for electric furnaces are available in several types. One type adjusts a saturable-core reactor which varies the current flow to the heating electrodes of the furnace; another type interrupts the current flow to

the furnace for various fractions of a cycle. They are available in single-speed floating control action and various combinations of proportional and proportional-speed floating actions.

**HYDRAULIC CONTROLLERS** may be operated by water pressure or from a separate oil-pressure supply system. The jet-pipe system is indicated in Fig. 9. Oil pressure is generated by the pump and the flow of oil passed through a movable nozzle; the oil jet impinges centrally on two receiving tubes. The measuring means, usually a pressure- or flow-measuring device, positions the jet pipe so that the oil is directed into one or the other of the two receiving tubes. This causes the piston in the operating cylinder to move in one direction or the other. The piston may be arranged to operate a valve or a damper. The action of a hydraulic controller is therefore proportional-speed floating, but other actions may also be obtained. An oil supply pressure of about 100 psig is used. The hydraulic controller is positive in action, and quite sensitive and accurate.

Because the hydraulic controller can create very large forces for the operation of large butterfly valves and dampers it is popular in power plants and combustion controls.

## 7. FINAL CONTROL ELEMENTS

The final control element is that portion of the controlling means which directly changes the value of the manipulated variable. The manipulated variable is that quantity or condition which is varied by the automatic controller so as to affect the value of the controlled variable. In controllers for temperature, pressure, flow, and liquid level, the manipulated variable is nearly always the rate of flow of a fluid. One exception is the temperature control of electric furnaces where the manipulated variable is the flow of electric current. The final control element for flowing fluids is usually a slip-stem valve, a rotary-stem valve, a butterfly valve, a gate valve, a louver, or a slide damper operated by an electric solenoid, an electric motor, a pneumatic diaphragm motor, or a pneumatic or hydraulic piston and cylinder.

**SLIP-STEM VALVES** are found in two types, the single-seated valve and the balanced double-seated valve. The single-seated valve is shown in Fig. 10. Its main advantage is that it can be made absolutely tight at shut-off. Double-seated valves are arranged so that the forces on the valve stem caused by the pressure differential are balanced. They cannot, in general, give absolutely tight shut-off. The slip-stem valve can be obtained with a variety of plugs or inner valves, among them the parabolic plug, the V-port plug, the bevel plug, and the rectangular-port plug. These variations are for the purpose of providing different flow characteristics and for handling different kinds of fluids.

Fig. 10. Single-seated control valve.

Valve bodies and plugs may be obtained in a wide variety of materials, such as brass, bronze, carbon steel, and stainless steel. For example, a valve specified with bronze body and stainless steel trim means that the valve body is made of bronze and the valve plug and valve seats are made of stainless steel. Slip-stem valves may be obtained in sizes from  $1/8$  in. to about 12 in. nominal diameter for pressure differentials up to about 1000 psi.

Slip-stem valves require a packing around the stem at the point where it passes out of the valve body. On valves handling corrosive fluids these packings require careful attention. Lubrication of the packing is usually supplied in order to reduce friction and leakage.

**ROTARY-STEM VALVES** are constructed much in the manner of the slip-stem valve except that the plug rotates in cylindrical seats in such a way that a rotary motion of the plug covers or uncovers an opening in the valve body. Otherwise their application is the same as for slip-stem valves. Rotary-stem valves are most commonly used with electric motor operators for the control of fuel oil to industrial furnaces.

**BUTTERFLY VALVES** consist of metal vanes rotating about their diameters inside a circular pipe, similar to the common stovepipe damper. The vane is operated by a shaft through a packing from a pneumatic diaphragm motor, an electric motor, or a hydraulic piston and cylinder. The butterfly valve, which is best for liquids or gases at low-pressure differentials, may be obtained in sizes (diameters) from 2 in. to about 60 in. A butterfly valve need not be opened more than 60 or 70 angular degrees from its closed position because little additional increase in flow is obtained beyond that point.

**PRESSURE DIFFERENTIAL** across the valve, louver, or damper is not an arbitrarily specified quantity. In operation a valve controlling the rate of flow of fluids is similar to an area flowmeter. Theoretically, the pressure differential remains constant while the area of the valve opening varies, thus changing the rate of flow. A small or zero-pressure

differential at a valve cannot be obtained, nor is it desirable from the standpoint of valve operation.

The pressure differential at the valve is determined by the pressure at the supply point of the fluid minus the pressure at the terminal point of the fluid minus the friction pressure loss in the piping between the valve and the supply and terminal points.

It is very important that the pressure differential at the valve remain constant. In most cases these conditions are impossible to obtain. Under any conditions the following rules are helpful:

1. The supply pressure of the fluid should be constant.
2. The pressure of the fluid at the terminal point should be constant.
3. The friction pressure loss in the piping should be a minimum.

## 8. PROCESS CHARACTERISTICS

A process comprises the collective functions performed in and by the equipment in which a variable is to be controlled. From the standpoint of automatic control the process includes only the part of the industrial operation or processing unit that relates the manipulated variable to the controlled variable for one automatic controller. In the industrial sense of the word, a process may contain several operations, each under automatic control.

Processes under automatic control exhibit the characteristic that the action of the manipulated variable on the controlled variable is dependent upon time; that is, the reaction of the controlled variable lags the action of the manipulated variable. These so-called process lags are the result of four process characteristics: **capacitance, resistance, dead time, and self-regulation.**

**CAPACITANCE** is the change in quantity contained per unit of change in some reference variable. Capacitance describes the ability of a process to absorb or store up energy.

**Thermal capacitance**, derived from specific heat and mass, is expressed in Btu per degree. For example, the thermal capacitance of 10 lb of water is 10 Btu per °F.

**Pressure capacitance** of a gas, derived from the gas laws, is expressed in cubic feet per pound per square foot. For a given pressure vessel 10 cu ft of gas may be required to raise the pressure by one pound per square foot when operating at a particular pressure. The pressure capacitance of the vessel would be 10 cu ft per lb per sq ft.

**Liquid capacitance**, derived from the area of a vessel containing liquids, is expressed in cubic feet per foot. In a tank of 10 sq ft area, 10 cu ft of liquid would be required to raise the level by one foot. The liquid capacitance of the tank would be 10 sq ft.

**RESISTANCE** is opposition to flow. It describes the ability of a body to cause a drop in potential when there is a flow through the body.

**Thermal resistance** for a specific body is the reciprocal of thermal conductivity and is expressed in the units of degrees per Btu per minute. For a sheet of asbestos, for example, 25 F temperature drop might be required to cause a flow of heat of 1.0 Btu per min. The thermal resistance of the sheet would be 25° per Btu per min.

Resistance for the flow of fluids can be expressed in pounds per square foot per cubic foot per minute, that is, a given resistance to flow in a pipe might require 150 lb per sq ft pressure differential to cause a flow of 1.0 cu ft per min. The resistance would then be 150 lb per sq ft per cu ft per min. The units of resistance for fluid flow can also be expressed in terms of feet head per cubic foot per minute. The units of process capacitance and resistance are shown in Table 1.

Table 1. Units of Process Capacitance and Resistance

Characteristic	Dimensional Symbol	Temperature	Pressure	Liquid Level
Quantity	W	Btu	cu ft	cu ft
Potential	V	Degrees	psf	ft
Flow	W/T	Btu/min	cu ft/min	cu ft/min
Capacitance	W/V	Btu/deg	cu ft/lb/sq ft	sq ft
Resistance	V T/W	Degrees/Btu/min	lb/sq ft/cu ft/min	ft/cu ft/min

**CAPACITANCE-RESISTANCE COMBINATIONS.** Capacitance in industrial processes is not always lumped at a particular point but may be distributed. Likewise resistance may be either lumped or distributed. In thermal processes, capacitance and resistance are nearly always distributed. However, upon analysis of the process, it is usually found that either the capacitance or the resistance of a body is its main consideration. For example, insulation on the outside of a steam vessel is mainly thermal resistance.

Its thermal capacitance is so small relative to the rest of the process that it can be safely ignored. On the other hand, a volume of well-agitated water in a vessel is mainly thermal capacitance, and its resistance effects can be safely ignored. In the flow of gas through a pipe the resistance and capacitance effects may be about equally distributed.

In analyzing processes containing a flow of liquid or gas, resistance effects represented by friction and obstructions in the line and capacitance effects represented by tanks can usually be considered separately.

The reaction of a process to a change in manipulated variable and without automatic control (called the reaction curve) is shown in Fig. 11. A process involving a single capacitance and a single resistance always exhibits a rate of change that is a maximum at the time the change in manipulated variable is made. Processes with more than one capacitance, each separated by a resistance from the other, and processes with distributed capacitance and resistance always exhibit a rate of change that is zero at first and gradually increases to a maximum.

Fig. 11. Process reaction curves.

For the purpose of analysis it is usually assumed that process capacitance and resistance are linear. This is usually not the case, but serious error can be avoided by using values of capacitance and resistance that are related to the operating point of the process.

**DEAD TIME**, any definite delay period between two related actions, is measured in units of time. It occurs in processes where it is necessary to transfer energy by means of solids or fluids flowing over a given distance at a given speed. For example, if a control valve is located 50 ft from the process and the average velocity of flow is 250 ft per min, a dead time of 0.20 min will exist.

A dead time as small as 0.01 min may be significant in the operation of the automatic controller. On the other hand, a dead time as large as 5.0 min is sometimes encountered.

**Self-regulation** is a sustained reaction inherent in the process which assists or opposes the establishment of equilibrium, illustrated in Fig. 12 for a liquid-level process. The process on the left has no inflow self-regulation because changes in level in the tank do not affect the rate of flow of liquid to the tank. This process has outflow self-regulation because as the level of liquid in the tank increases the flow out of the tank increases. A process with self-regulation always exhibits the characteristic that the potential level in the process will reach such an equilibrium point that inflow is equal to outflow. The reaction curve of such a process is exponential in shape.

The process on the right in Fig. 12 has no inflow self-regulation and no outflow self-regulation. With the constant displacement pump at the outlet, the outflow is constant and is not affected by changes in liquid level. Processes without self-regulation do not, therefore, reach an equilibrium point if the inflow is not equal to the outflow. The reaction curve for such processes, if they are linear, is a straight line.

In most thermal processes there is no inflow self-regulation, since the temperature in the process usually does not affect the supply of heat to the process. Thermal processes generally exhibit outflow self-regulation since the amount of heat carried out of the process is proportional to the temperature.

Processes involving pressure generally exhibit inflow self-regulation because the rate of supply of fluid to the process depends upon the pressure in the process. The existence of inflow and outflow self-regulation in pressure-type processes depends upon the method by which fluid is supplied to and taken from the process, and whether separate flow control of the fluid to the process and from the process is used.

Liquid-level processes likewise may or may not have inflow and outflow self-regulation, depending upon the method by which liquid is supplied to and taken from the tank.

In control of rate of flow of fluids self-regulation exists to a considerable degree.

Fig. 12. Process self-regulation.

### 9. APPLICATION OF CONTROL

Through experiences in the application of automatic control to various processes it has been found that certain processes exhibit certain characteristics and that particular kinds of automatic controllers perform best on particular processes. To summarize these experiences:

**Two-position control** is most satisfactory when:

1. The process has only a single capacitance.
2. Dead time is negligible.
3. The process reacts slowly.
4. The automatic controller operates rapidly.

**Single-speed floating control and proportional-speed floating control** are most satisfactory when:

1. The process has only a single capacitance.
2. Dead time is negligible.
3. The process reacts quickly.
4. Process self-regulation is large.
5. The automatic controller operates rapidly.

**Proportional control** is most satisfactory when:

1. Large disturbances are not present.
2. The process reacts slowly.
3. Multiple capacity effects are small.
4. The automatic controller operates rapidly.

**Reset action** must be used when disturbances exist at the process since it serves to reduce the offset in proportional control. Offset is a sustained deviation due to the inherent characteristic of a proportional controller action.

**Rate action** must be used when either multiple-capacity effect or dead time in a process is large. It serves to speed up the reaction of the process, stabilize it more quickly, and reduce the magnitude of deviation of the controlled variable.

Fig. 13. Stability of control.

the variable in not more than 2 or 3 cycles, producing the greatest stability with the smallest deviation.

**PRESSURE CONTROL.** For pressure control or pressure-reducing service in pipe-line systems the self-contained pressure regulator operates satisfactorily. Controllers of this type have proportional action with a small fixed proportional band. For gas flow, pressure changes causing flow changes in the pipe line are usually not very fast, multiple capacity effects and dead time are very close to zero, and process self-regulation is high. For pressure control of vessels and tanks proportional control action with either a pneumatic or a hydraulic controller is usually adequate. If load changes of appreciable magnitude exist, reset action should be added to the controller. For pressure control where the volume of the system is small or the flow large, as in draft systems, proportional-speed floating control action with a hydraulic controller is satisfactory.

**STABILITY OF CONTROL.** Proportional controllers and proportional-speed floating controllers and any of their combinations contain means whereby their response may be adjusted to produce the kind of action by the controller that is desired. These adjustments are usually made after the controller is installed on the process. Various degrees of stability in the controller are shown in Fig. 13. Generally there are different criteria in judging the stability action of a controller, depending upon the kind of process under control. A stable operation of the controller is desirable when the process is connected into a series of continuous processes so that the cycling or oscillation of the variable in one process will not affect the operation of subsequent processes. In this case it is necessary to sacrifice somewhat on deviation because it will be somewhat larger. In order to reduce the magnitude of the deviation it is sometimes desirable to make the control "tighter." This will reduce somewhat the stability of the control. An average best setting of the controller will stabilize

**FLOW CONTROL.** Quantity meters are not in common use for control of fluid flow. The orifice head meter and the area meter are most commonly used. With the orifice head meter it is best to arrange the control system so that the pressure most constant, either upstream or downstream, is one of the pressures at the orifice. For control of gas-flow rate, it is necessary that one of the differential pressures at the orifice should be absolutely constant. It may be necessary to use an auxiliary pressure controller to hold one of the pressures constant.

Proportional-speed floating control as in a hydraulic controller is best suited to flow control because the reaction of the flow rate to changes in valve position is fast, lags are small, and self-regulation is large. It should be noted that the main lags in flow control are those of the controller itself, particularly if a mercury manometer instrument is used. The same results may be achieved with the proportional plus reset action of pneumatic controllers, and it will generally be found that the proportional band of the controller will be large and the reset rate fast. Proportional control is not recommended for flow control.

**LIQUID-LEVEL CONTROL.** Two-position control of liquid level is often adequate if the area of the tank is large and a slight cycle in level is not objectionable. This can be accomplished with either an electric or a pneumatic controller. A great many float-type level controllers, self-contained, are used for liquid-level control where the float arm is connected mechanically to a balanced slip-stem valve. These controllers use proportional action and operate satisfactorily when the area of the tank is large. If the area of the tank is small or the through-flow is large a proportional-speed floating controller can be used. Pneumatic proportional control is satisfactory when the area of the tank is not small and when the through-flow is fairly constant. If the through-flow is not constant, a pneumatic proportional plus reset controller should be used.

**TEMPERATURE CONTROL** employs a wide variety of controllers, depending upon the results desired and the difficulty of the job. Most small heat-treating furnaces and high-temperature baths can be controlled satisfactorily with two-position control, using a thermocouple pyrometer or a radiation pyrometer with electric control. The main difficulty likely to be encountered is the measuring lag of the thermocouple element. The cycle of temperature which appears at the indicator or recorder will be less in amplitude compared to the actual changes of temperature as the measuring lag increases. Two-position control works best when the heating rate of the furnace is slow.

Single-speed floating control of furnaces and baths is adequate if the heating and cooling rates of the furnace or bath are fast.

When closer control of furnaces or bath temperature is desired, either electric proportional control or pneumatic proportional control can be used, provided that either the load changes are small or the heating and cooling rates of the furnace are small so that the proportional band of the controller will be narrow and the offset small. Reset action can be added to reduce the offset resulting from load changes. Rate action is usually not required for heat-treating furnaces and high-temperature baths.

For low-temperature baths, kettles, and heat exchangers there is a choice between the thermocouple pyrometer, the resistance thermometer, and the transmitting expansion thermometer. The selection depends upon cost and upon whether electric or pneumatic control is used. In such processes there will probably be an appreciable multiple-capacity effect, and in addition the measuring lag will probably not be small. In this case either electric proportional control or pneumatic proportional control can be used when the load changes are small. Reset response may be added to eliminate offset. Rate action may be required to overcome the multiple-capacity effect and the dead time.

For nearly all heat exchangers pneumatic proportional plus reset plus rate control is desirable because multiple-capacity effects are usually appreciable.

The application of automatic controllers is further summarized in Tables 2 and 3.

**Table 2. Application of Controller Actions**

Controller Action	Process Reaction	Multiple Capacity Effects and Dead Time	Process Disturbances	Process Self-regulation
Two-position	Slow	Very small	Small	*
Single-speed floating	Fast	Very small	Slow	Yes
Proportional-speed floating	Fast	Small	*	Yes
Proportional	Not fast	Not large	Small	*
Proportional + Rate	Not fast	*	Small	*
Proportional + Reset	*	Not large	Slow	*
Proportional + Reset + Rate	*	*	*	*

\* Factor not critical.

Table 3. Selection of Automatic Controllers

## PROCESS INSTRUMENTATION

Manufacturing processes can be divided into two general classes: flow or *continuous* processes and nonflow or *batch* processes. Every degree between completely nonflow and completely flow-type processes may be found in the processing industries, such as oil, chemical, heavy chemicals, plastics, rubber, power, ceramic, glass, food, textile, ferrous metals, nonferrous metals, and paper manufacturing.

The flow or continuous process is characterized by a careful balance of materials control at every point in the process. Automatic flow control is therefore the "heart" of flow processes.

For example, in modern central generating stations, where electrical power is generated from coal, the manufacturing operation requires a balance between incoming coal, water, and air to produce steam that must be passed to the turbo-generators at the required rate to produce electrical power in amount corresponding to the rate of consumption. The main effort of production control is, in this case, to maintain a complete balance in and between units of the plant.

The batch or nonflow process is characterized by operations dependent upon time or careful control of volume or weight, and frequently both. Time-program control, either manual or automatic, and liquid-level and pressure control are usually the "heart" of batch processes.

For example, in a food-processing plant operations are usually conducted in batches. In processing each batch, as in cooking, the time and quantity are of main importance.

## 10. PLANT LAYOUT

The layout of the plant is determined largely by the economics of the product and the method of manufacturing it. Instrumentation is sometimes the deciding factor in the selection of a particular plant layout because the effectiveness of production control, which is the basic purpose of instrumentation, is dependent upon plant layout.

**CENTRAL AND UNIT LAYOUT.** Central layout of plant and instrumentation is shown in Fig. 1. Here all control operations are grouped at a single control center, often called the instrument room or control room. In this center are located all the instruments and automatic controllers that can be conveniently gathered there. (See also Combined Transmitter Controllers, p. 18-37.) Central layout is commonly used in continuous processes. The advantages of a central layout are that all instrument service and maintenance are centered at one point, and coordination of all processing units is made easier.

Unit layout of instrumentation is shown in Fig. 2. The control center is divided into a number of units, located near a given processing unit or units. This arrangement is most often used in batch or semibatch processes. It is also used in continuous processes of large-scale magnitude where a single control center would be too unwieldy for adequate production control. The advantage of unit layout is that the control center is close to the processing unit which it serves so that maintenance and trouble shooting can be accomplished more quickly. Also the connecting lines from the instruments and automatic controllers to the control center are shorter.

**THE CONTROL CENTER** may vary in size from a large building containing hundreds of instruments and automatic controllers down to a small enclosure or cubicle for a few instruments. Sometimes the control center will be simply a small group of instruments mounted on a panel and located in the open near a processing unit. In considering the layout of the control center, the following factors are important:

1. The control center should preferably be completely enclosed.
2. Small control centers should have provisions for locking.
3. The control center must be clean and dry.
4. It must be temperature controlled and, in most cases, air conditioned.
5. It must be free from vibration.
6. It must be well lighted.
7. It must have an unfailing source of clean, dry air, of adequate pressure and capacity.
8. It must have an unfailing source of electrical power free of large surges in voltage and frequency.

These considerations apply to the control center whether or not it is housed in a separate enclosure.

It is desirable to make use of color dynamics, particularly in large control centers, in order to aid in the identification of vari-

ous sections of the control network. Instrumentation maintenance must be accomplished quickly, and it is often necessary to trace particular thermocouple leads and manometer or pneumatic control lines. Instruments, automatic controllers, and panel boards are usually black except in certain industries, such as foods, where white is preferred for appearance and cleanliness.

Fig. 1. Central instrumentation layout.

Fig. 2. Unit instrumentation layout.

Good coordination for the purpose of production control in a control center in a central layout and between control centers in a unit layout is not simple to achieve. Usually in large plants with either the central or unit layout a foreman is assigned to a particular group of instruments and automatic controllers controlling a particular processing unit. Coordination of the processing units is usually placed under a production-control manager. In small plants or units, particularly in batch processing, the control center is placed under the supervision of the process service operator.

Maintenance in large plants is usually directed from the control center. Service men may be stationed at the control center and may proceed to various points at the processing unit as the need arises. In even larger plants it has become necessary to station the service operators at a convenient point at the processing unit and direct these operators by telephone or "walkie-talkie" from the control center.

Maintenance in small plants is generally accomplished from a maintenance center subject to the call of the process operator.

**INSTRUMENTATION DIAGRAM.** A diagram can be made using the features of a process flow diagram but with all instrumentation and automatic control equipment outlined.

An instrumentation diagram should indicate (1) the variable being measured; (2) whether indication, recording, or other operations on the variable are required; (3) whether signaling of control functions are required; (4) any necessary auxiliary features; (5) type

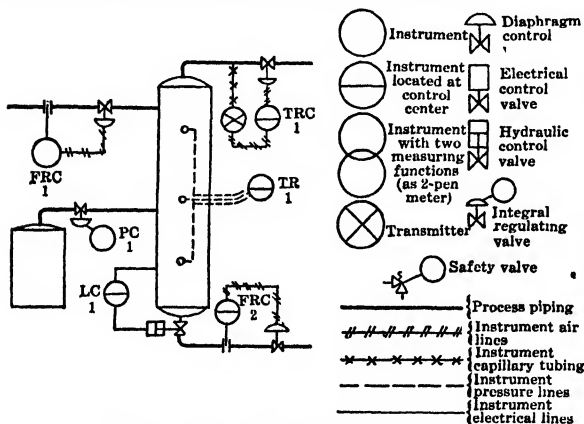

Fig. 3. Instrumentation diagram and symbols.

each piece of instrumentation equipment. These symbols have not, as yet, been standardized. However, a sample list is shown in Table 1, based on the tentative specifications of the Recommended Practices Committee of the Instrument Society of America.

Table 1. Instrumentation Diagram Symbols

First Letter	Second Letter	Third Letter
D Density	A Alarm	A Alarm
F Flow	C Control	C Control
H Hand-actuated	E Element (primary)	V Valve
L Level	G Glass (no measurement)	
M Moisture	I Indicating	
P Pressure	R Recorder	
T Temperature	S Safety	
	W Well	

**Examples:**

TRC-1 Temperature recording controller 1 on a given diagram.

FI-3 Flow rate indicating instrument, the third such instrument on a given diagram.

PCV-3 Valve for pressure controller 3; the instrument is "blind" (neither indicating nor recording).

An example of an instrumentation diagram is shown in Fig. 3, where the instrumentation symbols are shown. The diagram shows a schematic layout of the processing unit together with the necessary instrumentation.

The instrumentation diagram does not show exact location of equipment. For instruments which measure only, the general location of the measurement is given. For auto-

connecting lines; (6) location of point of measurement and point of control; (7) instrumentation at the control center and at the processing unit.

The purpose of an instrumentation diagram, however made, is to provide information quickly for use in process analysis, production control, and maintenance work. Therefore, it should not be loaded with useless information.

The main data of the instrumentation diagram are shown by means of symbols for

matic controllers the location of the point of measurement and the location of the final element are specified in a general manner, and lines connecting the final element, instrument, and measuring element are shown. The location of the instrumentation at a control center or on the processing unit should be shown.

## 11. PLANT DESIGN

Many modern industrial operations must be designed with automatic control of the materials flow and process performance for the reason that automatic controllers are able to make operations more accurate, repetitive, and reproducible. Measuring instruments automatically provide information on which can be based the production control of the operation.

Instrumentation cannot be considered too early in the design of the process. Do not wait until the process design is complete and then request an instrumentation engineer to control it.

**INSTRUMENTING THE PROCESS.** Process instrumentation should be considered at about the design stage of the process, before the equipment is designed and calculated, but after the research stage has passed. In some processes which require operation under critical conditions it is even necessary to consider the instrumentation in the research stage.

The method of instrumenting a process generally proceeds as follows:

1. List all variables that are important to process performance, such as temperatures, pressures, flows, time operations, and volumes.
2. Divide this list into four groups:
  - a. Variables neither measured nor controlled.
  - b. Variables to be checked periodically. (Specify the frequency of measurement.)
  - c. Variables to be continuously measured as an aid or check to performance.
  - d. Variables to be controlled.
3. Decide, with the design engineer, if it has not already been done, what type of plant and unit layout would be most efficient.
4. Construct an instrumentation diagram.
5. Prepare brief tentative specifications of instrument and control equipment from the instrumentation diagram.
6. Determine, on the basis of the instrumentation diagram, the performance to be expected of the instruments, considering such factors as:
  - a. The characteristics of the material being measured.
  - b. The measuring lag of the instruments.
  - c. The service maintenance of the instrument.
7. Determine, on the basis of the instrumentation diagram, the performance to be expected of the automatic controllers, considering such factors as:
  - a. The measured variable.
  - b. The manipulated variable.
  - c. The service maintenance of the controller.
  - d. The process load changes.
  - e. The process lags.
8. Complete the tentative specifications for instrument and control equipment.

The design and instrumentation of the process should then progress through the final stages, including pilot plant or model stages, with the necessary corrections and revisions made as need arises.

A process should neither be overinstrumented or underinstrumented. Experience has indicated that the slight extra effort to achieve a sound and adequate instrumentation of the process builds the confidence of both management and operators in production control by means of instruments and automatic controllers.

**PROCESS DYNAMICS.** With a view to automatic control, the process design can be made in such a manner that the dynamics of the process aids automatic control and vice versa. General rules are difficult to state because of the infinite number of combinations of capacitance, resistance, self-regulation, and dead time that can be selected. The following guides may be used in process design if their effects are carefully considered in each particular design:

1. The process should have one large capacitance.
2. All capacitances except the large one should be reduced to a minimum.
3. All resistances should be reduced to a minimum.
4. Dead time should be reduced to a minimum.
5. Self-regulation should be used whenever possible.

If it is necessary to design a process that will allow a high or fast rate of change of the variable, all capacitances and resistances must be reduced to a minimum. This process will probably be more difficult to control and will be affected to a greater extent by load changes.

Such examples as the following are pertinent. Countercurrent heat exchangers are usually easier to control than co-current types. The "soaking" or tempering effect in co-current heat exchangers, where the supply and heated fluids are nearly at the same temperature, introduces a dead time not conducive to good automatic control. Liquid level in a liquid-storage tank is easier to control if the tank is installed so that the liquid surface area is a maximum. Massive construction of the fire box of a gas or oil-fired furnace makes automatic control difficult because of excessive heat storage in the supply. The automatic controller may turn down the flame to minimum without greatly affecting the heat-transfer rate.

An evaluation of the process design in terms of process resistance, capacitance, and dead time will automatically lead the way to improvements in process-control characteristics. The mere recognition of the existence of the dynamic characteristics of a process is a step toward better instrumentation.

**PROCESS LOAD CHANGES** are the reason for the use of automatic control. On a processing unit there is one or more variables under control. The remaining variables affecting the performance of the process are not under control, and it is expected that the automatic controller will compensate for changes in uncontrolled variables. These are load changes. A change in the through-flow or output of the process may also be a load change.

In considering the load changes in the process the effects of ambient conditions such as thermal radiation and sun radiation, barometric pressure, relative humidity, and wind conditions should not be overlooked. Three characteristics of load changes that are important are their location, their magnitude, and their rate.

The location of the load change in the control loop and its effect upon automatic control depend entirely upon the particular design of the process. Therefore, no general rule can be stated as to the relative effect of load changes at different points.

The magnitude of the load change should, of course, be reduced to a minimum since the deviation of the controlled variable is directly proportional to the magnitude of the load change. If the magnitude of the load change is so large as to cause a large deviation of the controlled variable, a separate automatic controller should be considered for reducing the effect on the main automatic controller.

The rate of the load change is probably the most important characteristic. Fast or sudden load changes are next to impossible to overcome by an automatic controller operating by itself. For sudden load changes it is better to review the process or plant design to determine if they can be eliminated. Slow load changes can be counteracted by most automatic controllers if the process is not difficult to control.

Cyclic load changes often are difficult to overcome. The design of most thermal processes does not allow the automatic controller to act quickly enough to reduce the deviation of the controlled variable. From this standpoint thermal processes have either too much distributed capacitance or too large capacitance. On the other hand, in many flow or pressure processes the automatic controller may be too slow acting to overcome cyclic load changes. It is possible to have a sinusoidal load change of a frequency that equals the frequency of the control loop and synchronous oscillation results.

The magnitude of the process load or through-put also affects the operation of the automatic controller as does any other load change. In addition, a change in through-put as in a heat exchanger usually changes the dynamic characteristics of the process because of a change in capacitance or a change in resistance (heat-transfer film coefficients). In some cases a large change in process through-put is sufficient to require different controller actions at high loads and at low loads.

## 12. TRANSMISSION AND CONTROL

Because an instrument or automatic controller must be located at a distance from the processing unit, it becomes necessary automatically to transmit both the measurement of a variable and the control effect. The need for transmission is dictated by the layout of the processing unit and the location of the control center. Transmission is often used in either continuous or batch processes.

**TEMPERATURE-MEASUREMENT TRANSMISSION** is accomplished by different methods, depending upon the type of instrument in use. The transmitting expansion thermometer is not generally used with greater than 200 ft of capillary because of filling limitations and cost. The thermocouple pyrometer, the resistance thermometer, and

the radiation pyrometer have been generally used up to 500 ft distance between element and instrument and even up to 2000 ft in some cases. There is no practical limitation except the leadwire resistance which can be reduced by using heavier gage leadwire.

The addition of either pneumatic or electric transmission to the transmitting expansion thermometer allows the bulb to be placed up to 1000 ft distance from the instrument. With electric transmission there is little or no distance limitation. With pneumatic transmission, the measuring lag is increased at greater distances. In general,  $\frac{3}{8}$ -in. OD copper tubing for most pneumatic transmitters gives best results.

**PRESSURE, FLOW, OR LEVEL-MEASUREMENT TRANSMISSION** is usually accomplished by pneumatic means. Sometimes electrical transmission or hydraulic transmission is also used. Lines directly connected to pressure gages, flowmeters, and level meters should not be longer than about 25 to 50 ft (extremely variable, depending upon particular details). Long lines are costly, require extra maintenance and care, and are likely to cause a large measuring lag.

**AUTOMATIC CONTROL AND TRANSMISSION.** Controllers may be required to operate through long distances to the final element. Electric controllers such as the on-off and single-speed floating types are connected to solenoid valves or electric-motor valves. There is little or no limitation as to distance between controller and final element as long as the required voltage and current are available through the long leadwires. Electric proportional controllers using the Wheatstone bridge circuit are generally not used at distances greater than 1000 ft because of the resistance of the leads to the motor valve.

Pneumatic controllers will operate satisfactorily up to 500 ft distance between controller and final element, and even up to 1000 ft distance if the volume of the final element is small and if tubing of optimum size is used. A final element position device (positioner) should be used to increase the speed of operation. The optimum size tubing for connecting the controller to the final element is generally about  $\frac{3}{8}$ -in. OD copper tubing.

Hydraulic controllers will operate satisfactorily up to 500 ft and even 1000 ft distance between controller and final element.

**COMBINED TRANSMITTER CONTROLLERS** are coming into common use to avoid the lag imposed by transmission over long distances and also to unify the control center on large installations. The principle is shown in Fig. 4 for only one automatic controller. The automatic controller is constructed in such a manner that, although its control circuit operates in the normal manner, it is also able to transmit the measurement to a receiver at the control center. However, the control circuit (or loop) does not enter the control center. Thereby, the lags and delays encountered in transmission (particularly pneumatic transmission) are not included in the control loop. A set-point transmitter is used to effect the adjustment of the set point or control point of the automatic controller directly from the control center.

Where the control center is not too large, transmitter controllers may be of the indicating type and the receiver of the recording type. The control center is then constructed and employed in the usual manner.

For very large control centers, where unified production control is difficult, the transmitter controller may be a recording type and the receiver may be an indicator of the smallest possible physical dimensions. Thus several hundred indicators can be placed on a small panel space under the supervision of only one or two operators.

**REMOTE VALVE OPERATION** for manual setting can be accomplished by either electric, pneumatic, or hydraulic means. Valves, dampers, louvers, and other final elements may be operated by a solenoid valve or an electric-motor valve on the processing unit with a two-position push-button station at the desired point. Throttling the valve or damper may be accomplished with a "floating" electric-motor valve operator and an "inching" push-button station. There is practically no limitation on distance.

Pneumatic-valve operation is accomplished with a diaphragm motor or other pneumatic device positioning a valve or damper, and a small precision-type pressure regulator or transmitter. Pneumatic means is generally used for throttling a valve at distances of not over 1000 ft.

Hydraulic systems for remote operation can also be used. Some are very similar to

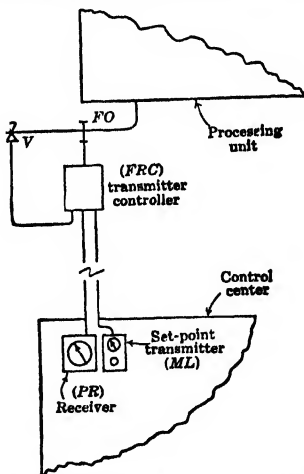

Fig. 4. Combined transmitter-controller.

the pneumatic type; others use a positive-displacement action. These are used for throttling action at any reasonable distance.

**SIGNALING, INDICATING, RECORDING.** Instruments and automatic controllers may or may not indicate the value of the variable which they measure. Often in industrial operations controllers are nonindicating (blind) simply because neither indication nor recording of the controlled variable is necessary. A good rule is never to use a recorder when an indicator will serve the purpose, and never to use an indicator when a non-indicating controller will suffice. In general, a recorder requires more maintenance than an indicator, and an indicator requires more maintenance than a nonindicating controller.

The purpose of a recorder is to provide a record or a history of past performance. A recording instrument without a chart in place is almost useless. Recording charts are nearly always kept in file as a record of process performance. Between circular-chart and strip-chart recorders there is little choice except personal preference. Circular charts are somewhat easier to file than strip charts, which are usually rolled. Circular-chart instruments show an 8-hour, 12-hour, or 24-hour performance at a single view on the instrument. Strip charts are easier to use when the variable must be recorded at a low position (lower 10 or 20%) on the scale or when a number of variables are to be recorded on a single chart.

Signaling is accomplished with an instrument arranged with contacts operating at several points on the instrument span. Electric lights, horns, or sirens may be used as necessary. For two-position signaling a red light signifies high or unsafe and a green light low or safe. Three-position and five-position signals may also be used. In general, it may be said that sufficient use is not made of this very simple and effective means of indication.

**CONTROL COMBINATIONS.** Often it is necessary to measure and control combinations of two variables or to control one variable in relation to another.

Fig. 5. Flow-ratio control.

**Ratio control** of two variables, such as the control of one flow rate to a desired ratio of another flow rate, is often used. Ratio of other variables such as temperature and pressure is less frequently required. It is accomplished (Fig. 5) by using one instrument with a transmitting means for adjusting the set point of an automatic controller. An adjusting mechanism is provided so that the second flow can be controlled to a given fraction (greater or less than one) of the first flow.

**Program control** is the control of a variable such as temperature to a desired value which varies with time. For example, in heat-treating furnaces and ovens it is often necessary to raise the temperature at a desired rate, hold it for a given time, and then cool at a certain rate as in annealing operations. This is accomplished by employing a cam or other means for adjusting the set point of an automatic controller to a fixed time schedule. Either thermometers or pyrometers may be used. In canning operations a pressure time cycle is sometimes required.

**Metered control** is employed for the purpose of obtaining more exact control where fluctuations occur in the manipulated variable, other than the desired changes required for automatic control. The fuel-flow control arrangement (Fig. 6) is particularly susceptible to pressure changes at the valve. In this case, a flow controller operates a valve and controls the flow to the desired value. The set point of the flow controller is adjusted by a temperature controller for controlling the furnace temperature. If pressure fluctuations occur in the flow line, the flow controller practically eliminates the effect of these changes on the temperature of the furnace.

**Difference Measurement.** The measurement of pressure differential (difference of two pressures) has been discussed. The measurement of temperature difference between two points can generally be accomplished by employing two thermocouples with the leads connected in opposition. A single instrument, usually a potentiometer, then operates from the difference in emf of the two thermocouples. Temperature difference can also be measured by using two resistance-thermometer bulbs in opposite arms of a resistance bridge.

Fig. 6. Metered control.

		Apparatus. . . . .	27

## ASME CODES

Tests to determine the performance of power-generating apparatus, or of equipment utilizing power, should be conducted under the Power Test Codes of the American Society of Mechanical Engineers. These codes prescribe the methods to be followed, the apparatus to be used, and the measurements and readings to be taken to determine completely the performance of power-generating or power-using apparatus.

Each type of apparatus is the subject of a separate code. In addition, supplementary information is published dealing with instruments and apparatus, whose use is common to all the codes. Complete copies of any code can be obtained from the American Society of Mechanical Engineers, 29 West 39th St., New York. Descriptions of codes in force are given herewith. A complete set of published Test Codes, and the Instruments and Apparatus Sections, may be purchased in two binders designed to hold them. The highest price of most individual codes, purchased separately, is about one dollar. A few are higher.

### LIST OF ASME POWER TEST CODES.

**Atmospheric Water-cooling Equipment** (Pub. 1930). Applies only to equipment used for cooling of the comparatively large amounts of water required for power or industrial purposes.

**Centrifugal, Mixed-flow and Axial-flow Compressors and Exhausters** (Pub. 1950). In addition to a number of corrections and revisions, this edition includes new rules for the testing of superchargers and axial-flow compressors, in which the change in the gas specific weight exceeds 7%, and also for testing apparatus handling gases other than air. The code establishes rules for conducting and reporting tests which will determine under specified conditions one or more of the following quantities: (a) quantity of air or gas delivered, (b) pressure rise produced, (c) power required for compression, and (d) efficiency of the compressor.

**Coal Pulverizers** (Pub. 1944). Defines practice of testing pulverizers used for firing boiler furnaces, kilns, or industrial furnaces of various types.

**Displacement Compressors, Vacuum Pumps, and Blowers** (Pub. 1950). These rules show how to determine the performance of all positive displacement compressors, blowers, vacuum pumps, and all rotary type machines which operate on a positive displacement principle.

**Dust-separating Apparatus** (Pub. 1941). Designed for testing all types of dust-separating apparatus installed for operation in conjunction with solid-fuel fired furnaces in order to determine overall efficiency; efficiency according to size of particles; pressure loss; dust concentration at the inlet and outlet of separator; combustible content of dust entering, leaving, and caught by separator; quantity of gas passing through the separator.

**Evaporating Apparatus** (Pub. 1941). The testing of single- or multiple-effect evaporators according to these rules provides information on: (1) adaptability of apparatus, (2) best method of operation, (3) capacity or efficiency or both of new installation preparatory to acceptance.

**Feedwater Heaters** (Pub. 1927). Applies to open and closed feedwater heaters.

**Fans** (Pub. 1945). For conducting tests on blowers, fans, and exhausters of the centrifugal, axial, or mixed-flow types in which the fluid density change through the machine does not exceed 7%. Specifies the practice for conducting tests of fans to determine (1) pressure, (2) quantity of air or other gas, (3) power supplied to the fan shaft, and (4) efficiency, all under specified conditions of fan speed and air density. Provides instructions for arrangement of test equipment such as ducts, plenum chambers, flow straighteners, and instruments. See also Section 1, Art. 23.

**Gas Producers** (Pub. 1928). Intended primarily for testing producers whose gas is to be used for power purposes.

**Gaseous Fuels** (Pub. 1944). For determining the chemical and physical properties which serve as indicators of the value of those gaseous fuels which are extensively used in the generation of heat and power, or whose efficiency of utilization is to be ascertained.

**Hydraulic Prime Movers** (Pub. 1949). A set of standard rules for the testing of an individual reaction or impulse turbine unit of any type.

**Internal-combustion Engines** (Pub. 1949). This new code meets current requirements for a dependable set of rules for testing all forms of reciprocating internal-combustion

engines, including gasoline engines, gas engines, and oil or dual fuel engines; and for evaluating the test results. Other recommendations cover the instruments, methods, and precautions to be employed.

**Reciprocating Steam-driven Displacement Pumps** (Pub. 1927). For determining the performance of the pump and engine, including reheaters, heaters, and jackets, if any, and jacket pumps, circulating pumps, condensate pumps, and vacuum pumps, which are concerned in their operation.

**Reciprocating Steam Engines** (Pub. 1935; reviewed and reaffirmed, 1949). Recommends standard testing methods for determining the performance of an engine, including steam jacket if any.

**Stationary Steam-generating Units** (Pub. 1946). For testing stationary steam-generating units defined as combinations of apparatus for producing, furnishing, or recovering heat, together with apparatus for transferring to a working fluid the heat thus made available. For purposes of this code such a unit may include boiler, water walls, water floor, water screens, superheater, reheater, economizer, air heater, furnace, and fuel-burning equipment. The code establishes rules for conducting tests to determine (a) capacity, (b) efficiency, (c) superheater characteristics, (d) any other operating characteristics. Instructions are given for two acceptable methods of testing for efficiency and capacity; (a) direct measurements of input and output, and (b) direct measurement of heat loss and either the input or output.

**Steam Condensing Apparatus** (Pub. 1938). Provides rules for determining (a) the absolute pressure the apparatus will maintain at the steam inlet nozzle when transferring heat rejected by the prime mover at a given rate in Btu per hour with a given flow and temperature of circulating water, and a given tube cleanliness, (b) thermal transmittance of surface condensers for given operating conditions, (c) the amount of undercooling of the condensate, (d) the percentage of dissolved oxygen in condensate.

**Steam Locomotives** (Pub. 1941). These two sets of rules outline (1) laboratory tests to determine the coal and steam consumption per unit of power when the locomotive is operated under fixed conditions, and (2) road tests to develop similar information under the conditions of road service. Consideration is given to measurements involved, instruments and apparatus required, preparations, operating conditions, duration of test, calculation of results, and method of calculating individual items.

**Steam Turbines** (Pub. 1949). This edition contains a number of revisions and changes, including important corrections in formulas for the determination of steam flow according to the enthalpy drop method. Rules provide for the testing of all types and applications of steam turbines, instruments to be employed and their applications, and methods of measurement. Instructions for determining the output of an electric generator driven by a steam turbine are also given.

**Appendix to Test Code for Steam Turbine** (Pub. 1949). The information in this 88-page pamphlet will facilitate the working up of test reports. Especially helpful are its numerical examples of many of the calculations involved in reporting tests conducted under the code rules, and filled-out hypothetical test forms.

**POWER TEST CODES BEING REVISED** are: Centrifugal and Rotary Pumps. Liquid Fuels. Refrigerating Systems. Solid Fuels. Speed Responsive Governors.

**ABSTRACTED MATERIAL.** Because it is impossible within reasonable space limits to quote each power test code completely, this section sets forth the general conditions of a few important codes. Selections have been made from these codes of only the more important material. In some instances portions of a paragraph have been deleted. It is necessary, therefore, that the reader consult the original code in any important case. The paragraph numbers of the original code are retained to facilitate reference, but since paragraphs have been deleted the numbers are not consecutive.

**INSTRUMENTS AND APPARATUS** bulletins are issued by ASME covering such broad fields as measurement of pressure, temperature, speed, flow, indicated horsepower, steam quality, time, linear measurements, surface areas, density, viscosity, humidity, smoke density, leakage, electrical quantities, and power. A few of the more important of the Instruments and Apparatus sections are abstracted herein, but for extensive information on even those abstracted, it is strongly recommended that the user consult the original Instruments and Apparatus sections.\*

It is ASME practice to revise codes in accordance with developments in the field covered by the respective codes. The user should, therefore, be certain that the most recent code is used. The dates of approval of the material quoted herein precede the text.

\* Most of the following material is abstracted from official ASME publications. The original codes and sections of Instruments and Apparatus publications were prepared by the ASME Power Test Codes Committee.

## INSTRUMENTS AND APPARATUS

### 1. TEMPERATURE MEASUREMENTS

(See Section 18, Instrumentation.)

### 2. SPEED MEASUREMENTS

(Approved, 1930)

Three methods of obtaining speed of rotating machinery are: (1) By a revolution counter and time piece. (2) By use of a tachometer. (3) By use of a stroboscope.

**COUNTERS** are instruments for determining number of revolutions or strokes of mechanisms. Continuous counters are used where a determination is sought over a considerable period of time. Hand counters are used for determinations over a short period. Continuous counters are of the following types.

A **direct-gearod counter** comprises a series of gears arranged to rotate a set of dials or pointers that register number of revolutions. It is positive, accurate, and reliable.

A **cyclometer-type counter** is the next best type. The set-back type counts one for each revolution. A set-back device permits returning all figures to zero. It will add when turned forward but may not subtract when rotated backward. It is not recommended for determinations exceeding 500 counts per min. The locked-wheel type counts one for each revolution and has no set-back device. It is recommended for high count determinations, and may be operated at twice the maximum speed of the set-back counter.

**Set-back rotary ratchet counters** count 10 for each complete forward rotation of the driving shaft, which is rotated by an oscillating motion of a lever. An oscillation of 40 to 60 degrees will count one on the number wheels. Backward rotation will not disturb the number wheels. These counters may be operated at 150 counts per min, and for short periods at 200 or 300 counts per min. Without the set-back attachment, it may be run continuously at twice its normal speed if the driving shaft is fitted with ball-bearings.

**Flat ratchet-type counters** involve reciprocating motion and a ratchet drive. Unless the travel is controlled overtravel may occur, especially at high speed. This type, limited to slow count determinations, is unsuited to high-accuracy determinations.

Continuous counters usually are fastened rigidly to the machine. The primary drive is operated by gear, chain, or flexible shaft in determining revolutions, or a system of continuous or intermittent linkages in determining number of strokes.

**Hand counters** may be of either the dial or cyclometer type. If carefully handled and well made, they are fairly reliable over a range of 200 to 2000 rpm. The possibilities of errors in these instruments are slippage between the shaft and the point of the instrument where contact is made and inaccuracy in determining time between making and breaking contact. The counter should be allowed to operate at shaft speed for a few seconds, and, as the dial passes zero, the stop watch should be started. After running for about two minutes, the stop watch should be stopped as the dial again passes zero. This will give the time for an integral number of revolutions and eliminate errors due to slippage and sudden starting or stopping. The longer the period, the less the error.

**THE TACHOSCOPE** is an instrument in which revolution counter and stop watch are mounted in one frame and arranged to operate simultaneously. The range varies from 0 to 5000 rpm. Its accuracy depends on the stop watch incorporated in it.

The **speed indicator** is an instrument operating on the same principle as the tachoscope, and averages the speed over a short period of time, indicating directly the speed in rpm. It may be used to measure speeds up to 30,000 rpm. The errors usually do not exceed 0.3 to 1.0% for readings taken in the upper part of the scale.

**TACHOMETERS.** A tachometer indicates speed directly and continuously. Tachometers are made in several different types. They have a substantially constant rpm error over the upper 70 to 80% of the working range, which usually is 0 to 2500 or 0 to 1200 rpm. In most types the readings should be in the upper 75% of the range and preferably in the upper 60%. The driving gear ratio can be changed to meet any actual speed range.

Tachometers may be driven by any one of the following methods, the first three being preferred: (1) Gear or chain. (2) Flexible shaft or cable enclosed in flexible housing. (3) Speed pin threaded into the end of the revolving shaft under observation, with a metal sleeve, slotted in both ends, for a driving link between shaft and tachometer. These three are all positive drives. (4) Adapter on tachometer shaft pressed into contact with a

so-called center on the rotating shaft of apparatus under test. (5) Belt and friction drive. This last method should be avoided as unreliable.

**Centrifugal tachometers** of the fly-ball and tilting-ring types operate through the centrifugal force produced by one balance ring or two or more revolving weights acting against springs. The compression of the springs moves the indicator or recorder pen. Good makes of this type of tachometer may have an error of 15 to 30 rpm between the range of 600 and 2500 rpm when new, and an error of 50 to 100 rpm, with a 25 to 50 or more rpm difference between up and down readings, after being in service for some time. The temperature effect may be approximately 1 rpm for each 10 F.

**Liquid pump tachometers** comprise a centrifugal pump, a reservoir for liquid, and an indicating tube into which the pump forces the liquid. Speed is determined by noting the position of the meniscus on the scale graduated in rpm. This instrument should be used only over the upper 40% of its range. The best instruments of this type, in good condition, can indicate speeds within 10 to 15 rpm at 6000 rpm.

**Air tachometers** are tachometers of the centrifugal type in which air is the working fluid as well as the transmitting medium. With it, indicating or recording mechanism may be located at a distance. An air tachometer should be used only in the upper 75% of its range. With a rotor making a maximum of 1500 rpm, it has an accuracy of 10 rpm when provided with a sensitive mechanism for indicating the air pressure produced and when operating under standard atmospheric conditions.

**The autographic hydraulic pump tachometers** use an autographic speed-recording mechanism which can portray speed changes incidental to changes of load, as in governor testing. It comprises three main elements, i.e., the tachometer pump, the indicating mechanism, and the auxiliary or return pump.

**Force-drag tachometers** depend on the drag produced by a rotating element which transmits a force from it to another movable part, to which the indicator needle is attached. The motion of the needle is limited by a spring. These tachometers are used largely on automobiles, but very little in power plant work. They are not recommended for use in connection with the Power Test Codes.

**Chronometric tachometers** comprise a repeating type of combination clock and revolution counter. They depend on direct revolution counting during an increment of time. They cannot be depended on closer than 6 to 7 rpm over the entire range of a scale of 2500 rpm maximum reading, and may have errors as great as 20 rpm when new, and an increased error of 5 or more rpm after a reasonable amount of continuous service, with possibility of complete failure.

**Electric tachometers** in commercial use are: (1) The electromagnetic type, consisting of a d-c generator with indicating volt meter. (2) An ordinary frequency meter calibrated to read speed instead of frequency. The electromagnetic type should be used with direct drive at not over 2500 rpm. Its accuracy is not closer than 20 rpm, and it may have a probable error of 0.5% for each 20 F temperature change.

The frequency meter tachometer may be of the vibrating reed type, the induction type, or the moving coil type. The reed type indicates only certain fixed speeds, corresponding to the individual reed, and these are rarely closer together than 0.5%. The range is from 800 to 12,500 rpm with an accuracy within 50 rpm for individual reeds when new. It may be accurate only within 100 rpm for individual reeds after use.

**Vibration tachometers** are similar in construction to vibrating reed frequency meter type tachometers, except that they depend only on the mechanical vibration produced by the rotating member. Their range and limitations are the same as those of the electrical instrument.

**STROBOSCOPES** utilize the persistence of vision when an object is viewed intermittently. The end of the rotating shaft under observation, or a disk attached to it, may be marked with several dots located equidistantly around the circumference of a circle whose center coincides with the center of the shaft. Vision is interrupted by using either a tuning fork arrangement or a rotating perforated disk driven by a separate machine. When sighting through a perforated disk, separately driven, the speed of this disk is varied until the marks or figures on the rotating shaft or disk appear to be stationary. Then the speed of the shaft under observation will be the same as that of the separately driven shaft, or some multiple of it, and equals (Indicated rpm  $\times$  number of holes in disk)  $\div$  (number of images). The number of images is the number of times a single mark on the indicating shaft is seen through all the holes in the disk of the adjusted-to-speed stroboscope. There is practically no limit to the range over which the stroboscope can be used.

## 3. PRESSURE MEASUREMENTS \*

(Approved, 1941)

**BAROMETERS** are used to measure pressure of the atmosphere. Readings, usually, are in inches of mercury. Barometric pressure plus gage pressure is the *absolute pressure*. Where measured pressure is less than atmospheric pressure, the pressure indicated by the reading of a U tube or vacuum gage is called the *vacuum*. The absolute pressure then is the difference between atmospheric pressure and the vacuum.

Mercurial barometer and mercury column readings always should be corrected to the value that would obtain if the mercury column were at 32 F. A calibration correction also should be applied. See below for methods of making these corrections.

The **mercurial barometer** is used generally and recommended. The diameter of bore of the glass tube of a barometer used under the test codes shall be not less than 0.25 in. The range usually is 25 to 32 in. Hg. Special barometers for mountainous regions begin at 15 or 20 in. A vernier attachment permits readings to 0.001 in., although for many engineering purposes readings to 0.01 in. are sufficiently accurate.

The **aneroid barometer** consists of an exhausted chamber whose ends are corrugated diaphragms. Atmospheric pressure on the diaphragms, balanced by a stiff spring, deflects them. The deflection is transmitted to a pointer which gives the reading, equivalent to that which would be given by a mercury barometer in inches or millimeters of mercury. Aneroid barometers are not as reliable as mercurial barometers, the temperature correction being uncertain. Their use is permissible only where accuracy in determination of barometric pressure is not of primary importance. The range of accuracy is 0.01 to 0.1 in.

The **recording barometer** or barograph is an aneroid barometer actuating a pen moving over a recording drum rotated by clockwork. It is subject to all the inaccuracies of the aneroid barometer, plus those due to the pen and its mechanism.

**Installation of barometers.** A barometer must be free from vibration, air currents, and violent temperature changes. It must be in good light, not directly exposed to the sun and not heated by nearby electric lamps. A mercurial barometer must hang free to insure a vertical position of the column. It must have a small vent to insure atmospheric pressure reaching the cistern.

**BAROMETRIC CALIBRATION AND CORRECTION. Obtaining Barometric Pressure from Daily Weather Maps.** Filed daily at all Weather Bureau stations, and in many post offices and other public places, are maps showing a set of "isobars" † or lines of equal barometric pressure, and "isotherms" or lines of equal temperature. These are for 7.20 A.M. Eastern Standard Time. Independent editions of the map are published at the principal Weather Bureau stations, such as New York, Boston, Chicago, and San Francisco, and copies for given days should be secured by application to the *nearest* such office.

If the station is at a different elevation from the barometer being calibrated, a correction should be made to compensate for this difference. Calibration also can be made by means of the weather maps. The location of the barometer is indicated by a dot on the map, and the barometric pressure is estimated by interpolation between the values shown on the two adjacent isobars. The following is an example of the calibration of a mercurial barometer at West Lynn, Mass.

Data	
Uncorrected barometric pressure	29.800 in. Hg
Check reading	29.801 in. Hg
Temperature	75 F
Height of cistern above floor	3 ft
Floor elevation above mean sea level	16.82 ft
Latitude	42.8 degrees N
Calibration	
Mean uncorrected reading	29.80 in. Hg
Temperature correction, Table 1	- 0.13 in. Hg
Elevation correction, Table 2	0.02 in. Hg
Gravity correction, Table 3	- 0.01 in. Hg
Corrected reading, reduced to sea level	29.68 in. Hg
Weather map reading, reported by Boston station of U. S. Weather Bureau reduced to sea level	29.67 in. Hg
Calibration correction	- 0.01 in. Hg

\* See also Section 18.

† Since January 1, 1940, isobars on all published weather maps have been labeled in millibars in addition to inches of mercury. 1015.9 millibars equal 30.00 in. Hg; 1 millibar equals approximately one three hundredths of an inch (0.0295); one tenth of an inch of mercury equals 3.4 millibars, approximately.

Observed readings of barometer shall be corrected by the data in Tables 1 to 3, or by Tables in U. S. Weather Bureau Circular F, or by the Smithsonian Tables. The following is an example of a mercurial barometer reading, correction, and reduction at West Lynn, Mass.

Uncorrected barometric pressure (actual reading)	29.80 in. Hg
Barometer temperature	75 F
Temperature correction, Table 1	— 0.13 in. Hg
Gravity correction, Table 3	— 0.01 in. Hg
Calibration correction ( <i>always</i> must be made)	— 0.01 in. Hg
Barometric pressure (at barometer elevation)	29.65 in. Hg
Level of barometer cistern <i>below</i> turbine center line	16 ft
Elevation correction, Table 2	— 0.02 in. Hg
Barometric pressure at elevation of turbine center line	29.63 in. Hg

Reduced reading,  $29.63 \times 0.4912 = 14.55$  psi = absolute barometric pressure at elevation of turbine center line.

**Temperature Corrections.** Table 1 is used to correct, for temperature, the readings of a mercurial barometer, mercury gage, or U tube. The correction reduces the reading to

\* This table is based on the values of the density of water given in the International Critical Tables, Vol. III, p. 24. It is assumed that the inches of water column are standard inches, which requires a correction, not given here, of the actual readings, for variation of the measuring scale with temperature.

gauge reading is below atmosphere and the gauge is set below the reference plane, or if the gauge reading is above atmospheric pressure and the gauge is above the reference plane,  $C$  is subtracted from the gauge reading. If the gauge reading is below atmospheric pressure and the gauge is above the reference plane, or if the gauge reading is above atmospheric pressure and the gauge is set below the reference plane,  $C$  is added to the gauge reading.

Gravity corrections need not be made for most engineering work, but Weather Bureau barometric readings always include a gravity correction. Hence the corrections in Table 3 are necessary for accurate calibration by comparison with a Weather Bureau reading.

Meniscus corrections are not necessary with barometers, the correction being allowed for in setting of the scale. For mercury columns comprising a reservoir and a single leg, or for mercury U tubes with legs of different diameters, the corrections of Table 4 should be added to the reading taken at the top of the meniscus.

Head and Water Column Corrections. For precise work, the mean of temperatures at inlet and outlet of apparatus under test must be used. Values of density of water at

\* Readings are to be multiplied by the multipliers indicated.  $d$  is density of water, lb per cu ft, at actual temperature (see Table 5). † At usual room temperature. ‡ For in. Hg at 32 F.

various temperatures together with multipliers for reducing readings in inches of water to pounds per square inch or inches of mercury are given in Table 5. For ordinary engineering work variation of density with temperature need not be considered, and density is taken as corresponding to usual room temperatures. Multipliers for conversion of barometer and U-tube readings are given in Table 6.

(The following material is abstracted from Chapter 2, *Supplement on Instruments and Apparatus*, ASME. Approved Nov. 1945. Numbers are from original code.)

### PRESSURE DEFINITIONS.

**1. Static pressure** is the force per unit area exerted on a wall by adjacent fluid (liquid or gas) which is at rest or which is flowing without disturbance along the wall of a conduit or main. It is measured by use of a *static hole* or *piezometer opening* in the wall, drilled perpendicularly to the surface adjacent to the fluid. *Static pressure* or merely *pressure*, as it is often called, must be distinguished from *total pressure* and *velocity pressure*.

**7. Total pressure** is greater than static pressure by an amount equivalent to the energy represented by the velocity of flow. It is exactly defined by the statement that frictionless, or isentropic expansion from fluid at rest with a pressure equal to the total pressure, into a region with pressure equal to the static pressure, would produce the existing velocity.

**8. Total pressure** is measured by use of an open ended tube pointing into the stream, known as an *impact tube*. The excess of total pressure as shown by an impact tube, over the static pressure, is the exact equivalent of the energy represented by the velocity, being the pressure rise due to perfect conversion of the velocity into pressure. This difference between total and static pressure is known as *velocity pressure* or *pressure equivalent of velocity head* or, sometimes, simply *velocity head*.

### STATIC HOLES.

**20. The size of static pressure holes** (sometimes called piezometer openings) for engineering purposes usually should be the tap drill for  $1/2$ ,  $3/8$ , or  $1/4$  in. standard pipe thread, or  $1/2$  to  $3/4$  in. diameter. Smaller holes may be used if sufficient care is taken and are recommended for smooth-bore conduits having diameters of 3 in. and less.

**23. A static pressure hole** shall be drilled at right angles to the surface of the wall adjacent to the fluid. The hole shall be straight and of uniform size for a length from the wall adjacent to the fluid, equal to at least two hole diameters.

**26. The lengths of straight main** given in the following shall be provided between static holes (or holes for impact tubes) and irregularities such as valves, reducers, elbows, scrolls, or casings of pumps and compressors, etc.

A length of straight main at least equal to 5 diameters shall be provided between a symmetrical irregularity such as a reducer or a sudden change in main size, and a succeeding pressure hole.

A length of straight main at least equal to 10 diameters shall be provided between the further end of an unsymmetrical irregularity such as an ell, globe valve, etc., and a succeeding pressure hole.

A length of straight main at least equal to 2 diameters shall be provided between a pressure hole and a succeeding irregularity of any kind.

**31. A piezometer ring** which consists of a circular chamber or tube surrounding a conduit and connected to it by a number of static holes has often been used to obtain static pressure. A single pressure-measuring instrument is then attached so as to give the static pressure at one point in the piezometer ring.

**32. A static tube** may be used to measure static pressure in the midst of a fluid in a main with undisturbed flow. The static pressure is constant through the body of the fluid, and usually the easiest way to obtain it is by means of a static hole in the main wall, so that a static tube should be rarely used.

### IMPACT TUBES.

**38. An impact tube** is a tube with an open end pointing directly upstream, which, when connected to a pressure-measuring instrument, gives *total pressure*.

**40. An impact tube** is shown in Fig. 1. It shall be inserted in the main so that the open end is at a distance equal to 0.15 of the conduit width from the wall. This places it at a point 0.7 of the distance from the center of the conduit to the wall, where the velocity is approximately equal to the average

Fig. 1. Recommended location of impact tube.

value. Lengths of straight main shall precede and succeed the tube as specified in Par. 26. The outer diameter of the tube should not exceed about 5% of the conduit width to avoid restriction of flow.

**46. The Pitot tube** (sometimes called *Pitot-static tube*) is a combination impact tube and static tube which gives both total and static pressure through independent pipes assembled together.

(The following material is from Chapter 4, *Instruments and Apparatus*, ASME. Approved Aug. 1938.)

#### GENERAL.

**1. Pressure and vacuum gages**, as ordinarily used, are instruments for measuring the difference between atmospheric pressure and the pressure in a main or apparatus.

**4. Bourdon gages** transmit the pressure to a curved elastic tube closed at one end. The tendency of the tube to "straighten out" when pressure is applied causes motion of the closed end, which is transmitted to the pointer. In indicating gages, the Bourdon tube sometimes covers an arc of about 300 degrees. In some gages there are two Bourdon tubes whose differential motion operates the pointer. In some gages the Bourdon tube is in the form of a spiral or helix with a number of complete turns.

**5. Bellows gages** transmit pressure to an elastic chamber formed with two or more diaphragms or a corrugated cylinder. This construction is used principally for low-pressure gages.

**6. Diaphragm gages** use a chamber with a flexible diaphragm on one side, whose motion is transmitted by a mechanism or a mercury column. This type of gage was formerly much in use, but it is being displaced by Bourdon gages.

Another similar type, known as a chemical or protected gage, has the chamber above the diaphragm with a connected Bourdon tube, filled with mercury, glycerin, or other liquid.

**47. Deadweight gages** may be used directly for accurate pressure measurement to avoid the necessity for frequent calibration of an ordinary gage. One proprietary form is described in *Power*, April 7, 1931, p. 567.

Ordinary deadweight testers may be used, if there is provision for an upper stop to prevent excess pressure from bouncing the piston and weights out on the floor.

(The following material is from Chapter 5, *Instruments and Apparatus*, ASME. Approved March 1942.)

**1. Liquid column gages**, sometimes referred to as manometers, have a U with glass legs partly filled with liquid. At the top of one leg is a *gage pipe connection* for attachment of a *pipe for pressure measurement* leading to a point where pressure is to be measured. The liquid rises in the other leg and the measurement of the difference in level gives the pressure. A vacuum is measured in similar manner, the liquid level rising in the leg to which the connection is made.

**3. Differential pressure**, or the difference between two pressures applied to the two legs of the U, is measured by a *differential U tube* or *differential gage* which has a *gage pipe connection* at the top of each leg.

**4. Absolute pressure** of a vacuum occasionally is measured directly by applying it to one leg of the U of an *absolute gage* which has a completely evacuated space at the top of the other leg.

**5. Vertical U tubes** are the simplest and most common of the many types of liquid column gages. They are called U tubes, mercury columns, water columns, manometers, U gages, inverted U tubes, etc.

**6. Single leg tubes** are another common type, having one leg of the U shortened and increased in cross section so as to form a well, cistern, or reservoir at the lower level, which is connected at the bottom to the glass leg in which the liquid rises. They are called single leg tubes, mercury columns, water columns, mercury gages, water gages, manometers, well type manometers, mercury pots, etc.

**7. Inclined gages or liquid draft gages** are similar to single leg U tubes, except that the glass leg carrying the liquid is inclined so as to increase the length of the scale to give a magnified reading of small pressures. Other instruments for measurement of small pressures are two-liquid U tubes, hook gages, micromanometers, and bell gages.

**24. Hook gages** have many forms. They consist of two chambers, usually having exactly the same area, connected at the bottom, and filled with water so as to form a U tube. The maximum pressure which can be measured is usually 4 to 6 in. of water. One of the chambers is closed at the top, and the pressure to be measured is applied to it. The other chamber, open to atmosphere at the top, is provided with a hook, raised and

lowered with a micrometer screw having a graduated head and scale, so as to give the level of the water to 0.001 in.

The hook gage is used primarily for calibrating inclined gages, bell gages, and the like. It may be used for direct measurement of very steady pressures.

**25. Micromanometers** are vertical, single leg tubes with change of liquid level given by adjustment of a micrometer screw reading to 0.001 or 0.0001 in. There are many forms.

**26. Absolute pressure gages** are mercury U tubes, one side being closed at the top and completely evacuated, and the other side connected to the vacuum to be measured. The difference in levels in the legs gives the absolute pressure and may be measured with suitable scales equipped with verniers and sliders.

Unless there is some precaution to preserve the evacuation, an absolute gage shall be used only a short time after evacuation or calibration.

## TEST CODE ABSTRACTS

### 4. TEST CODE FOR STATIONARY STEAM-GENERATING UNITS

(July 1946)

#### SECTION 1. OBJECT AND SCOPE.

**5. The purpose** of this code is to establish rules for conducting tests to determine: (a) Capacity. (b) Efficiency. (c) Superheater characteristics. (d) Any other operating characteristic.

**7. Instructions** are given for two acceptable methods of testing for efficiency and capacity. Method (a), the direct measurement of input and output, is the preferred method of testing and shall be employed in all cases where it is practicable to do so. Method (b), the direct measurement of heat loss and either the input or output, shall be used only where the direct measurement of both input and output is not feasible or cannot be made within acceptable limits of accuracy, or where this method is mutually satisfactory to the parties concerned. The method followed in conducting the tests shall be clearly defined in the report.

The fundamental measurements needed for the input-output method are the quantity and heat value of the fuel, and the quantity, and heat absorption per pound, of steam generated. It also is necessary that sufficient heat loss data be taken to permit checking the input-output results. The heat-loss method requires especial attention to all factors of importance in the evaluation of losses in relation to input: sampling and analysis of fuel, flue gas, flue dust, and refuse; measurement of flue gas temperature; and determinations of humidity of combustion air and loss due to radiation and convection.

**9. Method (a)** of this code is applicable to all conditions of steam generation, its practical application being limited only by the measuring facilities to be made available.

Method (b) of this code applies to all types of steam-generating units operating with either solid, liquid, or gaseous fuels. In cases of tests to be conducted under Method (b) where steam generators are designed for normal operation on mixed fuels it will be necessary to make special agreement between the interested parties as to the method of test, or to perform separate tests using the different fuels one at a time. If separate tests are run using single fuels, this code will apply. If tests are made using mixed fuels, the guiding principles and general intent of this code should form the basis of the special agreement between the parties concerned.

#### SECTION 2. ENUMERATION AND DESCRIPTION OF TERMS.

**12. Numerical Subscripts.** The diagram of a steam-generating unit, shown in Fig. 1, is intended to serve as a key to numerical subscripts employed throughout this code to indicate the point or location referred to.

**13. Letter Subscripts.** The letter subscripts have the following meanings:

<i>A</i> = air	<i>n</i> = net
<i>d</i> = dust, or stack refuse	<i>p</i> = pit refuse
<i>f</i> = fuel	<i>s</i> = steam
<i>g</i> = gross	<i>w</i> = feedwater
<i>G</i> = gases of combustion	<i>x</i> = auxiliary

The chemical symbols are also used in some cases as subscripts.

With so many quantities involved and so many points of reference, it has been found impossible to restrict the code to the use of single subscripts. Where both letter and numerical subscripts are used, the numerical one is given second, for example,  $W_{at}$ .

**48. Test and Run.** In order to eliminate the possibility of misunderstanding which might be caused by the use of the word "test" to mean either the entire investigation or one of its subdivisions, throughout this code the word "test" is applied only to the entire investigation, and the word "run" to a subdivision. A run consists of a complete set of observations made for a period of time with one or more of the independent variables maintained virtually constant.

### SECTION 3. GUIDING PRINCIPLES.

#### 53. Items on Which Agreement Shall Be Reached.

The parties concerned in the test shall reach a definite agreement as to the specific objectives of the test.

Often the boiler proper and the different accessory parts of the steam-generating unit, such as fuel-burning equipment, air heater, and water-cooled walls of the furnace, are supplied by different manufacturers. This tends, in some cases, to complicate the responsibility for the performance guarantees. For instance, the manufacturer of the fuel-burning equipment might have given efficiency guarantees for the entire unit, based in part on assumed or guaranteed performance values for the heat-exchange apparatus. Even with only one manufacturer supplying the entire unit, it may be that not all the performance values given in the contract are guaranteed. It is not uncommon to see guarantees made at only one rate of output (usually the maximum continuous) and the other values labeled "expected performance." An agreement shall be made prior to the test which specifically allocates respective responsibilities for all performances and the operating conditions which are to be considered as part of the conditions of the test.

Unless otherwise specified, efficiency shall be understood to mean gross efficiency. By agreement, however, the acceptability of a steam-generating unit may be based on the net efficiency, in which case the Appendix shall be followed.

In tests conducted to determine capacity characteristics the interested parties shall agree to a carefully prepared definition of the word "capacity" as it is intended to apply to the particular test.

Unless otherwise agreed, the thermodynamic properties of steam and water shall be taken from current editions of *Thermodynamic Properties of Steam*, by Keenan and Keyes, or *Vapor Charts*, by Ellenwood and Mackey.

Agreement shall be reached as to any instruments or methods of measurement to be employed which are not prescribed by this code. Any such deviations from the prescribed rules shall be fully explained in the test report.

**57.** The parties to the test shall agree upon a laboratory of recognized standing to make the necessary fuel analyses. Duplicate samples shall always be kept so that in case of mishap to the original samples duplicates will be available.

**59. Preparation for Test.** An acceptance test shall be undertaken only when the manufacturer or manufacturers certify that the unit is operating to their satisfaction and is, therefore, ready for test. Especially in the case of the fuel-burning equipment, adjustments and sometimes changes are necessary to obtain optimum performance. The preparations for an acceptance test preferably should be started as soon as the unit is in satisfactory condition for test, provided the load and other governing factors are suitable. Delays for longer periods may require maintenance in addition to cleaning in order to reproduce substantially new conditions.

**60.** In the case of an acceptance test all heat-transfer surfaces, both internal and external, shall be thoroughly cleaned before starting the test. During the test, only the normal cleaning shall be allowed.

The furnace setting, gas and air conduits, casing of the economizer and of the air heater shall be checked for leakage. Any leaks detected shall be stopped before the test is started.

**62. A preliminary run shall be made for purposes of:**

- (a) Checking the operation of all instruments.
- (b) Training the observers and other test personnel.

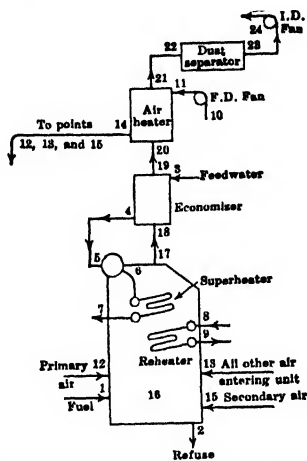

FIG. 1. Diagram of steam-generating unit showing locations in all circuits that correspond to numerical subscripts of the code.

- (c) Making minor adjustments, the needs for which were not evident during the preparation for test, and establishing proper combustion conditions for the particular fuel and rate of burning to be employed. If the manufacturer has passed upon the suitability of the equipment for test, as required in Par. 59, he shall be a party to such adjustments.

After a preliminary run has been made, it may be declared an acceptance run, upon mutual agreement, provided that all the requirements of a regular run have been met.

**63. Starting and Stopping.** Combustion conditions, rate of feeding fuel (also quantity of fuel on grate if hand or stoker-fired), rate of feeding water, water level in drum, excess air, and all controllable temperatures and pressures shall be, as nearly as possible, the same at the end of the run as at the beginning. These, and any other conditions in which variations might affect the results of the test, shall be caused to attain and hold the closest practical approximation to constancy for whatever period may be required to assure that the temperatures of the refractories of the setting and all other parts of the equipment have reached equilibrium before the run is started and shall be so maintained throughout the run. The time required to attain stabilization or equilibrium with respect to temperatures will vary widely with the design of the unit and character of materials in the setting, but, in general, at least three hours of operation at the output to be maintained during the run should be allowed for stabilization purposes. In some instances it may be necessary to terminate a run prematurely because of inability to maintain one or more of the above conditions at the desired value. The conditions which will call for terminating a run should be agreed upon before starting the test.

**64. Duration of Runs.** For determining the efficiency of a steam-generating unit when hand or stoker-fired, runs by Method (a) preferably should be of at least 24 hours duration. However, if conditions make it advisable or necessary, the length of a run may be reduced, but not to less than 10 hours, nor to a period less than that required to burn a total of 500 lb per sq ft of grate area. The longer the duration of runs the less will be the possibility of significant error from difference in water level or due to estimating the difference in amount of unburned fuel on the grate at the beginning and end of the run. In many cases it is difficult to estimate the change in thickness of a large fuel bed closer than 3 in. When the ratio of ash to unburned fuel is also indeterminate, the final estimate of effective change in thickness will frequently be in error by as much as 4 in. The possible error due to estimating the effective change in the amount of unburned fuel on the grate at the beginning and end of each run should be considered in determining the duration of each run. Runs by Method (b) shall be of at least four hours' duration.

For units fired with liquid or gaseous fuel, the runs preferably should be of not less than 10-hour duration; when conducted by Method (a), Par. 7, they shall be not shorter than 6 hours, and when conducted by Method (b) they shall be not shorter than 4 hours. These requirements apply also to pulverized fuel, provided the unit-mill system is used and, for tests conducted by Method (a), provided the fuel can be weighed as it is fed to the mills. For those stations having a centralized pulverizing plant, it is practically impossible to weigh the fuel fed to any one unit. In some cases a bunker can be segregated and the amount of fuel consumed during the run can be determined from the difference in amount of fuel in the bunker at the beginning and end of the run. Where Method (a) is used for such tests, the runs shall be of sufficient length to reduce the error due to estimating the amount of fuel fired to less than 1%.

For waste-heat boilers efficiency runs shall be for not less than 6 hours.

**65. Number of Runs.** For purposes of an acceptance test at least two runs shall be made approximately at each selected load. It is desirable, but not mandatory, that runs be made at not less than four loads so that a curve may be drawn to relate the test points, the loads being selected so as to embrace the load or loads for which guarantees are made.

**66. Frequency and Consistency of Readings.** Except for quantity measurements, the readings shall be taken at 15-min intervals. If, however, there are sudden and wide fluctuations, the readings shall be taken at 10-min intervals, or at such frequency as may be necessary to determine the true average. Where the amount of fuel or feedwater is determined from integrating instruments, a reading shall be taken every hour. If these quantities are weighed, the frequency of weighing is usually determined by the capacity of the scales, but the intervals shall be such that a total can be obtained for each hour of the test. The time of dump of each hopper of coal or of each tank of feedwater shall be recorded. The indicating element for venturi tubes, nozzles, or orifice plates shall be read at 5-min intervals or more frequently when the fluctuations are large.

**67. Rejection of Runs.** Should serious inconsistencies in the observed data be detected during a run, or during the computation of results, the run shall be rejected in whole or in part. A run that has been rejected shall be repeated if necessary to attain the objectives of the test.

**SECTION 4. INSTRUMENTS AND METHODS OF MEASUREMENT.**

**68. The necessary instruments and mandatory rules for making measurements are prescribed herein.** Specific references are made to ASME Power Test Codes, to Supplements on Instruments and Apparatus, and to other publications describing detailed methods and apparatus which shall be employed in testing stationary steam-generating units under the code. This code is confined to the essential requirements which shall be followed except with special agreement to the contrary. (See Section 3, Guiding Principles.)

The instruments generally required for an acceptance test of a steam-generating unit are included in the following list, which is presented merely for check purposes. Only those instruments necessary to attain the desired objective need be used, together with any others, not listed, which may be necessary.

- (a) For Input Quantity Measurement: fuel-weighing scales, weigh hoppers, weigh laries, weighing tanks, volumetric tanks, flowmeters, etc.
- (b) For Output Quantity Measurement: scales, weigh tanks, volumetric tanks or flowmeters, to measure quantities of steam generated and/or reheated.
- (c) For Quality of Saturated Steam at Boiler Outlet and Reheater Inlet: suitable sampling and measuring apparatus.
- (d) For Total Solids Determination in Steam: suitable sampling and conductivity apparatus.
- (e) For Temperature of Steam at Superheater Outlet, Reheater Inlet, and Reheater Outlet: suitable temperature-measuring instruments.
- (f) For Temperature of Feedwater Entering Economizer, Leaving Economizer, and Entering Boiler: suitable temperature-measuring instruments.
- (g) For Steam Pressure at Boiler Drum, Boiler Outlet, Superheater Inlet, Superheater Outlet, Reheater Inlet, Reheater Outlet: Bourdon Gages, Deadweight Gages.
- (h) For Feedwater Pressure: Bourdon Gages, Deadweight Gages.
- (i) For Flue Gas Analysis at All Required Points: suitable apparatus for sampling and analysis.
- (j) For Flue Gas and Air Temperatures: suitable thermometers, pyrometers, etc.
- (k) For Flue Gas and Air Pressures: suitable manometers.
- (l) For Flue Gas and Air Quantity Measurements: suitable flowmeters.
- (m) For Refuse Measurement: suitable scales and containers.
- (n) For Dust Measurements on Air, Fuel Gas, or Flue Gas: suitable sampling and separating apparatus.
- (o) For Smoke-density Measurement: acceptable charts and other apparatus.
- (p) For Auxiliary Energy Measurement: the necessary electrical instruments, orifices, nozzles, thermometers, pressure gages, etc.
- (q) For Fuel Temperature Measurement: the necessary thermometers and wells.
- (r) For Fuel Pressure Measurement: suitable gages and manometers.

**SOLID FUEL.**

**69. Quantity Measurement.** Fuel shall be weighed near the point where it is to be used. All loss of fuel between the point of weighing and the point of introduction to the equipment under test shall be eliminated or measured and accounted for to the satisfaction of all parties concerned. The weighing scales shall be checked prior to and after the test and caused to weigh to an accuracy within 2 in 1000 in the range of loads weighed. Checks and calibrations shall be made in accordance with Instruments and Apparatus, Part 5, Measurement of Quantity of Materials. Permissible types of scales are: weigh hoppers (stationary or traveling); platform scales in conjunction with suitable containers such as wheelbarrows or cars; and track scales. Complete emptying of hoppers, cars, or other containers between weighings shall be assured or proper corrections made. Amount of fuel in the bin or hopper to which the weighed fuel is discharged shall either be the same at the start and at the conclusion of the run (within limits satisfactory to the interested parties), or this bin or hopper shall be empty at the start of the run and the fuel remaining at the end of the run shall be dumped, weighed, and allowed for.

Arrangement and operation of fuel-weighing equipment shall preferably be such that checks on consumption during each hour of the run can be made as a matter of convenience and guide. Only the totals, however, are to be used in the final calculations.

**70. Sampling.** A representative sample of fuel shall be obtained in accordance with the Test Code for Solid Fuels. Loss of moisture due to strong drafts at the point of sampling (such as may occur at a pulverizer feeder for example) shall be guarded against. Samples of air-borne pulverized fuel shall be obtained as described in the Test Code for Coal Pulverizers, which requires sampling on traverses 90 degrees apart in the cross section of the fuel duct. The sampling time at each point should be proportional to the area repre-

sented by that point,\* and the recovery should lie within limits of 90 to 110%, i.e., the rate of sampling should be so adjusted that the weight of the sample is to the total weight of the fuel as the cross-sectional area of the sampling tip is to the cross-sectional area of the fuel duct, within limits of  $\pm 10\%$ .

**71. Determination of Fuel Characteristics.** Analysis and heat value determination shall be made in accordance with the Test Code for Solid Fuels, and Supplement on Instruments and Apparatus, Part 9 on Heat of Combustion. Fineness determination shall be made as specified in the latest revision of ASTM Standard Method of Sampling and Fineness Test of Powdered Coal, D-197-30, or by such superseding method as may be adopted by the ASME. Determination of such characteristics as grindability, etc., shall be in accordance with appropriate ASTM methods.

#### LIQUID FUEL.

**72. Quantity Measurement.** Liquid fuel quantity measurements shall, if possible, be made by weigh tanks or volumetric tanks. Meters may be used only upon agreement between the interested parties and shall be carefully calibrated under conditions simulating those existing during the test in regard to grade of oil, temperature, pressure, rate of flow, and meter position.

Leakage between point of measurement and point of firing shall be either eliminated or measured and accounted for. Branch connections to the piping shall be either blanked off or provided with valves and suitable tell-tale drains for detecting leakage. Leakage from valve stuffing boxes shall be eliminated. Any unavoidable leakage from pump stuffing boxes, or elsewhere, shall be collected and accounted for. In the event that the fuel piping leakage can be neither eliminated nor made small enough so that with due regard to possible influence on test results it may be ignored, the test shall be conducted in accordance with Method (b), Par. 7, for acceptance under this code.

Practice and precautions relative to the use of weigh tanks and volumetric tanks for liquid fuel measurement shall be those stated in Pars. 78 and 79.

**73. Sampling.** A representative sample of fuel shall be obtained in accordance with the Test Code for Liquid Fuels.

**74. Determination of Fuel Characteristics.** Analysis, high-heat value, density, viscosity, etc., shall be determined in accordance with the Test Code for Liquid Fuels, Instruments and Apparatus.

#### GASEOUS FUEL.

**75. Quantity Measurement.** Measurement of the relatively large volumes of gaseous fuel normally encountered in steam-generator testing requires the use of meters of the orifice, nozzle, or Pitot type. These methods of measurement should be undertaken only by those with knowledge and experience in the technique involved.

Pitot tube construction and operation shall be in accordance with Instruments and Apparatus.

The recommendations of Instruments and Apparatus shall be followed with reference not only to the design, construction, calibration, and use of flow nozzles and orifices, but also to their location, installation, and use in the pipe line and the installation of the connecting piping system between the primary element and the manometer. All computations of flow rate from the observed differentials, pressures, and temperatures shall be made in accordance with the provisions of Instruments and Apparatus.

If compressor pulsations or flow irregularities from control or regulating equipment are present, the differential pulsation shall be checked with a pulsometer, and, if in excess of 20 per cent of the average differential in amplitude, shall be reduced to this limit by introduction of capacity and resistance between the source of pulsation and the flow nozzle or orifice plate or by other means before measurement is considered acceptable.

Pressure of the gas at point of volume determination shall be measured by a suitable manometer as described in Instruments and Apparatus. Temperature shall be measured with thermometers in accordance with Instruments and Apparatus.

**76. Sampling.** The gas shall be properly sampled in accordance with the Test Code for Gaseous Fuels.

**77. Determination of Fuel Characteristics.** Gaseous fuel characteristics shall be determined in accordance with the Test Code for Gaseous Fuels; Instruments and Apparatus.

#### OUTPUT MEASUREMENT.

**78. Weigh Tanks.** The preferred method of measuring output is by weighing the feed-water. With suitable weigh tanks an accuracy of  $\pm 0.2\%$  can be expected. If the quantity of water evaporated is measured by any method other than direct weighing, the measuring

---

\* Sampling will be simplified if the sampling points are arranged to represent equal areas, thus making the sampling time the same for each point.

apparatus, its calibration and operation shall be agreed upon by the interested parties and fully described in the test report.

The water-weighing apparatus or other output measuring devices shall be arranged in an accessible place and made as convenient as possible.

Weigh-tank scales shall be calibrated over the entire range of loads at which they are to be used.

It shall be ascertained that inlet and outlet valves do not leak when closed.

The tank system shall be free from external force, so nothing can affect the weight reading except the tare and the water to be weighed. Tare shall be checked before each filling.

After each dumping it shall be made certain that dribbling has ceased before the outlet valve is closed.

Design, construction, calibration, and operation of weighing tanks shall be in accordance with Instruments and Apparatus.

**79. Volumetric Tanks.** Suitably designed volumetric tanks are capable of an accuracy within  $\pm 0.5\%$ .

Volumetric tanks shall be calibrated prior to the test with weighed increments of water at some fixed temperature. In the use of the tanks, suitable allowance shall be made for difference between the temperature of the water weighed and the temperature during calibration, cognizance being taken of thermal expansion of both the water and the tank metal.

The precautions given in Par. 78 shall be observed wherever they apply to volumetric tanks.

Design, construction, calibration, and operation of volumetric tanks shall be in accordance with Instruments and Apparatus.

**80. Venturi Tube, Flow Nozzle, or Thin-plate Orifice for Feedwater.** Feedwater quantity may be measured by venturi tube, flow nozzle, or thin-plate orifice upon agreement by the parties to the test.

The recommendations of Instruments and Apparatus shall be followed with reference not only to the design, construction, calibration, and use of flow nozzles and orifices, but also to their location, installation, and use in the pipe line and the installation of the connecting piping system between the primary element and the manometer.

Venturi tube, nozzle, or orifice design shall be such that the differential pressure as shown by the manometer is at least 6 in. of mercury.

If fluctuations in flow due to a reciprocating pump or other source of pulsation are present, these fluctuations shall be reduced to not more than 10 per cent of the average flow by the introduction of a cushion chamber, surge chamber, or other means of absorbing the surges between the source of pulsation and the primary device before measurement is considered acceptable.

Differential pressure from the primary device shall be measured by two complete manometer systems which shall check within  $1/2$  per cent of the differential pressure, except that by agreement among all interested parties a single manometer and set of taps may be used. At least one manometer of a two-manometer system, and the calibrating manometer, if required, shall be in accordance with Instruments and Apparatus. If a single manometer is used, it shall be in strict accordance with Instruments and Apparatus and shall be calibrated before and after the test as specified therein. A commercial flowmeter may be used in place of one manometer of a two-manometer system, or by agreement for the single manometer of a one-manometer setup.

**81. Flow Measurements of Steam.** The output quantity may be determined by means of nozzles or thin-plate orifices upon agreement by the parties to the test.

The recommendations of Instruments and Apparatus shall be followed with reference not only to the design, construction, calibration, and use of flow nozzles and orifices, but also to their location, installation, and use in the pipe line and the installation of the connecting piping system between the primary element and the manometer.

Differential pressure from the primary device shall be measured by two complete manometer systems which shall check within  $1/2$  per cent of the differential pressure, except that by agreement among all interested parties a single manometer and set of taps may be used. At least one manometer of a two-manometer system, and the calibrating manometer if required, shall be in accordance with Instruments and Apparatus. If a single manometer is used, it shall be in strict accordance with Instruments and Apparatus and shall be calibrated before and after the test as specified therein. A commercial flowmeter may be used in place of one manometer of a two-manometer system, or by agreement for the single manometer of a one-manometer setup.

If pulsations due to reciprocating engines or flow irregularities from control or regulating equipment are present, the differential pulsation shall be checked with a pulsometer, and, if in excess of 20 per cent of the average differential in amplitude, shall be reduced to this

limit by introduction of capacity and resistance between the source of pulsation and the flow nozzle or orifice plate or by other means before measurement is considered acceptable.

#### **FLUE GAS SAMPLING AND ANALYSIS.**

**86. Sampling Locations.** Analysis of the exit gases is the usual practice, but frequently analyses are required at other points. There may be considerable variation in gas analysis over the cross section of the gas passage due to stratification and air infiltration. The best practical method of obtaining a true sample is to divide the cross section of the gas passage into equal areas and to take velocity measurements and gas samples from the centers of these component areas. A weighted average can then be calculated, taking into consideration the gas temperature (Par. 90) as well as the velocity.

#### **GAS AND AIR TEMPERATURE MEASUREMENTS.**

**90. Flue-gas Temperature.** Flue-gas temperature is normally measured at the boiler outlet, economizer outlet, and air heater outlet but may in certain instances be measured at other points such as at the inlet to a waste-heat boiler.

Because of stratification, the accurate determination of flue-gas temperature generally requires that temperatures at several points over the cross section of the gas passage be measured and averaged. Number and location of the points depend upon the size and shape of the passage and upon the variation in temperature and velocity over its cross section. A preliminary survey of the passage shall be made as a guide in the location of temperature measurement points.

**COMPUTATIONS.** The section of the code covering computations is too lengthy for inclusion herein. The reader should consult the complete code.

## **5. TEST CODE FOR STEAM TURBINES**

(Approved Sept. 14, 1948)

### **SECTION 1. OBJECT AND SCOPE.**

**1. The purpose** of this code is to establish rules for conducting tests of a steam turbine to determine the following: (a) Capacity. (b) Steam or heat consumption. (c) Engine efficiency. (d) Emergency governor operation.

**2. This code** provides for the conduct of tests and for the computation and tabulation of the results, for turbines of the following types:

- (a) Complete expansion condensing turbines in which all the steam enters at one pressure and all the steam leaves at a pressure less than that of the atmosphere.
- (b) Condensing turbines similar to (a) except that the steam is reheated after partial expansion.
- (c) Condensing turbines similar to (a) but operating on a regenerative cycle, i.e., steam being extracted from one or more stages solely for heating the unit's own feedwater. This class may include turbines that supply extraction steam for heating make-up feedwater, also evaporators and deaerators serving as extraction feedwater heaters.
- (d) Condensing turbines similar to (a) but provided with both the special features described in (b) and (c).
- (e) Noncondensing and back-pressure turbines in which all steam enters at one pressure and all steam leaves at a pressure equal to or greater than that of the atmosphere.
- (f) Condensing extraction turbines in which some of the entering steam is extracted at one or more points after partial expansion, for purposes other than heating their own feedwater, the remainder leaving the exhaust flange at a pressure less than that of the atmosphere.
- (g) Noncondensing extraction turbines in which some of the entering steam is extracted at one or more points after partial expansion, for purposes other than heating their own feedwater, the remainder leaving the exhaust flange at a pressure equal to or greater than that of the atmosphere.
- (h) Condensing mixed-pressure turbines, in which steam is admitted at two or more pressures to two or more points, at the same time or at different times; all steam leaving the exhaust flange at a pressure less than that of the atmosphere.
- (i) Noncondensing mixed-pressure turbines, in which steam is admitted at two or more pressures to two or more points, at the same time or at different times; all steam leaving the exhaust flange at a pressure equal to or greater than that of the atmosphere.
- (j) Combination extraction and mixed-pressure turbines (f) and (h) or (g) and (i).

### **SECTION 2. DESCRIPTION AND DEFINITIONS OF TERMS.**

See code for complete definitions. Selected symbols given in text as required.

**SECTION 3. GUIDING PRINCIPLES.**

**81. Items on Which Agreement Should Be Reached.** The parties to the test must reach a definite agreement as to its specific object and must agree as to the method of operation, that is, the intent of the contract or specification in this respect, upon which the guarantees have been based. They shall ascertain all the specified or contract operating conditions and warranties for all the values that are pertinent to the object of the test. Any omissions or ambiguities as to any of them in the contract or specification are to be eliminated or their values or intent agreed upon before the test is commenced.

**83.** Agreement must be reached as to the method of calibration of instruments and by whom.

**87.** The parties to the test may designate a person to direct the test and serve as arbitrator in event of disputes as to the accuracy of observations, conditions, or methods of operations.

**88.** Accredited representatives of the purchaser and the builder may at all times be present to verify that the tests are conducted in accordance with this code and the agreements made prior to the tests.

**89.** An acceptance test should be undertaken within two months of the time the turbine is first put into commercial service, provided no serious operating difficulty has been experienced. In any event, except with written agreement to the contrary, the acceptance test shall take place within the maintenance period specified in the contract.

**90. Tolerances.** This code does not include consideration of any over-all tolerances or margins on steam or heat consumption, or on engine efficiency guarantees written in a contract. The test results shall be reported as calculated from the test observations, instrument calibrations only having been applied.

**91. Preparation for Test.** Previous to an acceptance test, the turbine unit shall be placed at the disposal of the manufacturer for examination in order that he may ascertain that it is in a suitable condition for the conduct of an acceptance test. There must be assurance that nozzles and blading are free from scale or foreign matter.

**92. Preliminary tests** may be run for the purpose of: (a) Determining whether the turbine is in a suitable condition for the conduct of an acceptance test. (b) Checking all instruments. (c) Training personnel.

**93.** Unless otherwise agreed, for both preliminary and acceptance tests, the turbine shall be in commercial operating condition.

After a preliminary test is made, if mutually agreed, this test may be considered an acceptance test, provided it has complied with all requirements for an acceptance test.

**102. Operating Conditions.** Every effort shall be made to run the tests under the specified conditions such as output, pressures, temperatures, etc., in order to avoid as far as possible the application of corrections to the test results, some of which may be of doubtful accuracy.

**109. Duration of Test.** The duration of the test shall be such as to make it possible to obtain several check readings. Each test need continue only for a time sufficient to insure accurate and consistent results as required for certain of the measurements prescribed in Section 4, Par. 192.

**114. Corrections** shall be applied to the test results for any deviations of the test conditions from those specified. Correction factors for deviation of the operating conditions from those specified may be in the form of curves or numerical values. The method of applying corrections shall be carried out as required in Section 5.

**115.** The numerical values of corrections are preferably stated in the contract; if not, they shall be agreed upon by the parties to the test prior to the test. If mutually agreed upon by the parties to the test, auxiliary tests may be run for the purpose of determining the value of certain of the correction factors. Any such special tests shall be completely described in the test report, as to the methods employed and the results obtained.

**SECTION 4. INSTRUMENTS AND METHODS OF MEASUREMENT.****Measurement of Mechanical Output**

**121.** Absorption or transmission dynamometers are permissible, provided precautions are taken in their construction and use to insure accuracy. Included are electric or eddy-current generators, the input of which is measured by the reaction of the stator.

The dynamometer is preferably arranged so that the reaction due to friction of any bearings that are essentially a part of the dynamometer will be automatically included in the dynamometer readings. Otherwise the parties to the test shall agree upon an allowance for these losses which shall be stated in the test report.

## Electrical Output Measurement

**131.** The net output of a turbine-driven generator is defined by the following formula:

$$\left[ \begin{array}{c} \text{Net} \\ \text{output} \\ \text{(kw)} \end{array} \right] = \left[ \begin{array}{c} \text{Electrical} \\ \text{power output} \\ \text{of generator} \\ \text{(kw)} \end{array} \right] - \left[ \begin{array}{c} \text{That portion of} \\ \text{the excitation power} \\ \text{that is separately} \\ \text{supplied (kw)} \end{array} \right] - \left[ \begin{array}{c} \text{Power for ventilation} \\ \text{and other auxiliary} \\ \text{service if separately} \\ \text{supplied (kw)} \end{array} \right]$$

The excitation power (kw) is the product of the current (amperes) supplied to the generator field and the sum of the voltage drops across the generator field and main field rheostats (volts), divided by 1000. Only that portion of the excitation power which is separately supplied from a source external to the turbine generator unit is to be charged against the prime mover.

If any generator auxiliary power service, such as that for driving ventilating fans, cooling water pumps, or lubricating oil pumps are electric motor driven, the power input to the motors shall be deducted from the main turbine generator output.

In the case of a steam rate test, if any generator auxiliary is engine or turbine driven, the auxiliary drive steam flow shall be added to the test steam flow of the main turbine, with no deduction from the main generator output.

In the case of a heat rate test, if any generator auxiliary is engine or turbine driven, the heat flow chargeable to the main turbine shall have added to it the heat flow chargeable to the auxiliary drive, with no deduction from the main generator output. This addition is the product of the steam flow to the auxiliary drive and the difference between the enthalpy of the steam supplied to the auxiliary drive and the enthalpy of saturated liquid corresponding to the measured exhaust pressure of the auxiliary drive.

**132. Method of Power Measurement.** For 3-phase a-c generators with grounded neutral, the power output of the main unit shall be measured by the 3-wattmeter method. For 3-phase a-c generators with isolated neutral, the power output of the main unit shall be measured by either the 2-wattmeter method or the 3-wattmeter method, either method being suitable. The power output of single-phase a-c generators shall be measured by the 1-wattmeter method. The power output of d-c generators shall be measured by the d-c voltmeter-ammeter method.

**134. Instruments.** Portable precision indicating wattmeters or watthour meters checked "in-place" shall be used with appropriate current and potential instrument transformers for measuring the electrical power output. Portable indicating ammeters and voltmeters shall be included in the measuring circuits to establish that the generator load conforms to rated conditions during the test, and to measure the current, voltage, and power factor for use in calculating the ratio and phase-angle corrections of the instrument transformers.

## Steam Quantity Measurement

**140. Turbines, Type (a) or (b).** If the test is a steam or heat rate test, or an engine efficiency determination of a complete expansion or reheating turbine, type (a) or (b), the measurement may be made by:

- (a) Actual weighing of the condensate discharged from a surface condenser by means of tanks and suitable scales, with the understanding that the limits of possible error may be  $\pm 0.25\%$ .
- (b) By measurement of the condensate discharged from a surface condenser by means of calibrated volumetric measuring tanks, with the understanding that the limits of possible error may be  $\pm 0.50\%$ .
- (c) By a steam flow measurement of the initial steam by means of nozzles or thin-plate orifices, provided the steam remains superheated not less than 25 F during its passage through the nozzle or orifice and upon agreement by the parties to the test and with the understanding that the limits of possible error may be  $\pm 1.50\%$ .
- (d) By a flow measurement of the condensate discharged from a surface condenser by means of either a nozzle, a thin-plate orifice, or venturi tube, upon agreement by the parties to the test and with the understanding that the limits of possible error may be  $\pm 1.25\%$  and provided that during the passage of the water through the nozzle, orifice, or tube, either (1) the pressures remain not less than 50 psi above the vapor-pressure corresponding to boiling at the measured temperature, or (2) that the temperatures remain not less than 25 F below the boiling temperature corresponding to the lowest measured pressure.
- (e) By means of a gravity tank arranged to receive the condensate pump delivery and having one or more calibrated nozzles in the base thereof combined with water-level

measuring means, said nozzles discharging freely to the atmosphere. The quantity is determined from the measurement of head in the tank, together with the measurement of elapsed time, with the understanding that the limits of possible error may be  $\pm 0.50\%$ .

**141. Turbines, Type (c) or (d).** If the test is a heat rate test, or an engine efficiency determination of a regenerative turbine, type (c) or (d), with extraction feedwater heaters included in the turbine guarantees, the measurement may be made by the means prescribed in item (c) of Par. 140, or

- (f) By measurement of the feedwater discharged from the final heater or by measurement of condensate or feedwater at any point of the condensate or feedwater system where its flow is equal to that discharged from the final feedwater heater by means of either a nozzle, orifice, or venturi tube, as prescribed by item (d) of Par. 140.
- (g) By measurement of the feedwater discharged from the final heater by any of the means prescribed by items (a), (b), or (e) of Par. 140, provided the water temperature does not exceed 175 F, or, for the purpose of the test, its temperature is reduced by means of a heat exchanger to a value not exceeding 175 F.
- (h) By removing the condensate or feedwater from any point intermediate the heaters or intermediate a heater and the condensate pump where the temperature does not exceed 175 F, determining its quantity by means of a gravity tank (item [e] of Par. 140), and returning the water to a point between the same heaters with the precaution that the quantity measuring means are such that the flow through the succeeding hotter heaters is continuous and can, at all times, be maintained equal to the flow from the condenser. This requirement renders the use of weighing or volumetric tanks somewhat difficult. They may be employed, however, provided agreement is reached as to limits of possible error, and provided the weighing or volumetric tanks discharge into a secondary tank, whence the water is pumped to the next succeeding hotter feedwater heater by means of a pump, the delivery of which can be controlled. The mean level in the secondary tank before and after each discharge should be maintained approximately constant. The limits of possible error are dependent upon maintaining constant mean level in the secondary tank.

**148. Extraction Feedwater Heaters.** Condensate drains from heaters may be cascaded or delivered by other means to a point in the condensate system upstream of the point of measurement, provided this is consonant with the specification, contract, or intended method of operation. Disturbing the intended method of operation in this respect affects the flow to certain of the heaters so that the turbine operates under conditions other than those specified or intended. It is, therefore, sometimes necessary in the case of turbines types (c) and (d) to determine independently the condensate flow from certain extraction heaters.

**149. Feed Heaters Steam Flow.** The independent determination of steam flow to, or condensate flow from, a feedwater heater may be made by:

- (a) A flow measurement in the line between the heater condensate pump and the feed line by the means and precautions prescribed by item (d) of Par. 140, or
- (b) By a measurement of the rate of feedwater flow before it is joined by the heater condensate and measurements of the pressure and temperature of the heater condensate and the feedwater flow both before and after they join, provided the rise in temperature of the feedwater by the heater condensate is not less than 5 F and that the actual temperatures or the temperature difference can be measured within 0.2 F.
- (c) By measurements of the pressure and temperature of the steam supplied to the heater (applicable only if such steam is superheated), the temperature of the heater condensate, the feedwater flow through the heater, and the pressures and temperatures of the water entering and leaving the heater.

#### Nozzles or Thin-plate Orifices for Measuring Steam or Water Quantity

**160.** Measurement of the flow of steam or water in a pipe by means of nozzles or thin-plate orifices should be undertaken only by those with knowledge and experience in the technique of such measurement and with the understanding that for a steam measurement the limits of possible error may be  $\pm 1.5\%$  and for a water measurement,  $\pm 1.25\%$ .

**161.** The technique of the method shall be carried out in detail as given in Instruments and Apparatus. This includes the selection of proper dimensional standards for nozzles and orifices, the use of the prescribed standard pressure tapping means for measuring the differential pressure, and the application of the prescribed formulas and coefficients for

calculating steam or water flow. If these and the following precautions are observed, flow measurements may be made without calibration of the nozzle or orifice.

**162.** The ratio of nozzle throat or orifice diameter to pipe diameter shall not exceed 0.65.

#### Venturi Tubes for Measuring a Water Flow

**176.** For the measurement of water flow by a venturi tube, according to the means prescribed by item (d) of Par. 140 or item (f) of Par. 141, or for any flow the value of which influences the results of the test, the following precautions shall be followed:

**177.** Prior to the test, the tube shall be calibrated either by weighing the flow or by means of volumetric measuring tanks. The calibration shall be carried out over the range of flows and temperatures that will obtain during the tests.

**178.** Reynolds' number as calculated for the pipe flow shall be not less than that at which the flow coefficient is known to remain sensibly constant.

**179.** During calibration and test there shall be not less than 10 diameters of straight pipe upstream of the tube and not less than 3 diameters of straight pipe downstream of the tube. In both cases the diameters of the pipes shall be the same as that of the inlet and outlet of the tube.

#### Enthalpy Drop Method

**188.** In determining a steam flow according to the enthalpy drop method, the pressure and temperature of the initial steam and of the steam at the exhaust flange shall be measured with all the precautions required herein for pressure and temperature measurements. The temperatures may be determined by thermocouples, resistance thermometers, or mercury-in-glass thermometers, as may be agreed upon by the parties to the test. The precaution shall be taken that the means of measuring exhaust temperature is as little as possible affected by radiation or conduction to or from other portions of the turbine. It is for this reason that the enthalpy drop method may be employed only for turbines in which the flow at rated output is not less than 50,000 lb per hr. The exhaust pressure and temperature shall be observed at a number of points at the exhaust outlet according to the provisions for exhaust pressure measurements for condensing turbines.

**190.** The electrical, windage, and friction losses of the generator shall be computed from actual independent tests. The mechanical losses of the turbine may be calculated. Among these are:

- (a) Friction of bearings.
- (b) Power to revolve gland parts.
- (c) Windage of all rotating parts that are external to the turbine casing.
- (d) Power to operate lubricating oil pumps, speed-regulating mechanisms, and any other apparatus that is included in the steam or heat consumption guarantees.
- (e) Heat loss by radiation, conduction, and convection.

The parties to the test shall assign and agree upon all these losses and shall state their values in the test report.

**192. Duration of Tests.** (a) For weighed or measured quantity of condensate or feed-water including a flow measurement of the same by any of the methods permissible herein and including the calibration of nozzle blocks removed from the turbine, the duration of the test shall be not less than three hours. This period may be curtailed upon agreement by the parties to the test, provided successive measurements at equal time intervals referred to constant output do not differ one from another by more than 1.0%.

(b) For the flow measurement of initial steam by means of a flow nozzle or an orifice in a thin plate or by means of first stage nozzle blocks that have been removed from the turbine and calibrated prior to the test, or for a steam flow determination by the enthalpy drop method, the duration of the test shall be for not less than twenty consecutive sets of simultaneous readings, occupying not less than 20 min.

(c) For a test to determine capacity, the duration of the test shall be not less than 15 min and shall comprise not less than five consecutive sets of simultaneous readings of output and the operating conditions as to pressures, temperatures, etc., that are required herein for consumption tests. Operating conditions shall remain sufficiently constant so that readings of the same values do not differ one from another by more than 2.0%. (See Par. 289.)

**202.** Vigilance shall be employed to discover sources of leakage which shall be either isolated, or measurement shall be made of them and proper allowances made therefor in the computation of results.

Among other sources of leakage may be the following:

- (a) Extraneous or unused piping connections.
- (b) Condensate pump leakage.
- (c) *Ejector steam* unless the turbine guarantees include the operation of the ejectors.

Because this quantity is relatively small, it may be calculated from the measured areas of the nozzles and the steam conditions.

- (d) *Make-up Feedwater.* For turbines type (c) or (d), if the turbine performance guarantees do not include specific provision for an amount of make-up feedwater and it is impracticable to operate the plant without admitting make-up feedwater, it is desirable that make-up be supplied to the boiler separately from the turbine condensate system. If this is impracticable, corrections shall be made to the test results. (See Par. 297.)
- (e) *Surge tank,* if any, in connection with the condensate or feedwater system, should, if practicable, be disconnected and regarded as an unused connection.
- (f) *Exhaust steam from auxiliaries,* if they discharge into the turbine or condenser system and the guarantees are not based on the inclusion of this steam, shall be diverted elsewhere for the period of the test. If this is impracticable, this steam consumption shall be determined. Because the amounts are relatively small, it is sufficient to measure it by means of a calibrated steam meter during the test of the main unit, provided the steam flow is steady as in the case of a turbine drive. With unsteady flow, as with reciprocating engine drives, a separate steam consumption test of the auxiliaries shall be made with precautions that the operating conditions shall be the same as obtain during the test of the main unit.
- (g) *Water seals* when they cannot be supplied from condensate.
- (h) *Water seal overflow* or leakage which is not returned to the condensate before the condensate is weighed or measured, if condensate is employed for sealing.
- (i) *Steam escaping from glands, including valve stems, etc.,* if not agreed negligible by the parties to the test. This quantity may be condensed by any means and allowance made therefor in the computation of results.
- (j) *Steam removed with air* by the air-removal means, if it is agreed by the parties to the test to be not negligible, as in the unusual case of disproportionately large air-removal means being employed. In such a case, the method of measurement of the quantity shall be agreed upon by the parties to the test.
- (k) *Drips and drains* shall be (1) treated as unused connections, (2) returned to the condensate, or (3) cooled and weighed and allowance made therefor in the computation of results.
- (l) *Water sealed atmospheric relief valves.*
- (m) *Water sealed condenser connections.*
- (n) *Water cooled stoker parts, etc.,* employing condensate.
- (o) *Overflow outlets* from water seal tanks.

## SECTION 5. COMPUTATION OF RESULTS.

**254. Total Steam.** Allowance must be made in the steam quantity measurement for:

- (a) Condenser leakage.
- (b) Water, other than condensate, condenser leakage, or make-up feedwater, entering the condenser.
- (c) Condensate which does not pass to the quantity measuring means.
- (d) Steam entering the condenser that has not been supplied to the turbine. (See Par. 202.)

**255. Correction of the Test Result to Specified Conditions.** Corrections should, if possible, be avoided by carrying out the test under the specified conditions. If the object of the test is to ascertain whether the turbine fulfills the performance guarantees under the specified conditions, the corrections to be applied should be agreed upon beforehand. (See Pars. 114 and 115.) It is far more satisfactory, however, to conduct a test under the specified conditions than to apply corrections which may be of doubtful accuracy.

After all efforts have been made, it may still be impossible to have every condition as desired, and the test results must be corrected so as to give, as nearly as possible, the values which would have obtained with specified conditions.

Correction values are preferably stated in the contract, if not they shall be agreed upon by the parties to the test before tests are commenced. If mutually agreed upon, separate tests may be carried out for the purpose of determining the value of certain of the corrections according to the requirements of Pars. 267 and 274.

When any of the corrections take the form of curves (not straight lines) for the variable, a smooth correction curve, without any abrupt changes of slope, should be drawn through the agreed correction values for the various points. The percentage correction between the specified and test value for the variable shall be taken as a single-valued slope between the two points on the curve.

**260.** A test of a steam turbine shall not be completed or if completed shall not be regarded as official, unless specifically agreed upon by the parties to the test, if the total

arithmetic sum of all of the percentage corrections, regardless of the direction of the individual correction exceeds the following percentages:

Condensing and noncondensing turbines, types (a), (b), and (e)	10%
Regenerative turbines, with or without reheating, types (c) and (d)	15%

**267. Correction Tests.** Tests to determine correction values, if conducted (see Par. 115) will consist of runs with each of a series of values of the condition in question, with all other conditions except output as near as possible to the specified values.

Alternatively, correction tests, except those for initial pressure, may be run by maintaining steam flow substantially constant, i.e., by operating with constant turbine inlet pressure in which case the output will become variable.

**274.** The correction curves shall finally be plotted so as to show the test values of steam rate as ordinates for various values of a variable condition as abscissa. A straight line often represents the points but sometimes a curve must be drawn. The slope of the straight line or of a chord of the curve (the chord being drawn between test value and specified value of the variable) divided by the specified steam rate gives the percentage correction. Often a curve is also drawn with the loads which existed for each correction test as ordinates and the variable condition as abscissas.

### Capacity Tests

**289.** The net output for each observation is to be corrected for the deviation of pressures, temperatures, etc., from the conditions of the test to those specified, as provided for in the case of steam or heat consumption tests. The test report shall state the average of the net outputs of the test, including the average of all the test operating conditions. The report shall also state the average of the corrected net outputs, including all of the operating conditions to which the test has been corrected. (See Par. 192[c].)

**290. Average Performance.** Guarantees of performance and the results of tests covering a series of outputs may be expressed as a single value based on weighted steam, heat consumptions, or engine efficiencies, for example:

1	2	3	4
Percentage of Rated Output (Example)	Steam or Heat Consumption, lb or Btu per kw-hr or Engine Efficiency	Factor (Example)	Product of Columns (2) and (3)
100	.....	3	.....
80	.....	4	.....
60	.....	3	.....
40	.....	2	.....
		12	Sum

$$\text{Weighted average} = \frac{\text{Sum of column 4}}{\text{Sum of column 3}}$$

Fig. 2. Temperature-entropy diagram showing locations in the cycle corresponding to numerical subscripts.

The above percentages of rated output and their respective factors should be embodied in the contract, and established to suit the load conditions under which it is expected the turbine will operate. If not embodied in the contract, they shall be agreed upon by the parties to the contract, before any tests are commenced.

The temperature-entropy diagram (Fig. 2) is intended to serve as a key to the numerical subscripts employed in the code, for reheating and regenerative condensing turbines, types (b), (c), and (d).

It is assumed that the pressure rise in the condensate pump is small, so that the accompanying rises in temperature and enthalpy of the condensate are negligible. In the diagram, the temperature rise has been grossly enlarged. All references to point 5 in this code assume that the temperature and the enthalpy of the condensate are sensibly the same on the inlet and on the discharge side of the condensate pump.

## Steam Rates

**291.** For a complete expansion turbine, type (a), the steam rate under stated operating conditions, as to pressures, temperatures, output, etc., is:

$$\text{Steam rate, lb steam per kw hr} = \frac{W_1}{P_g \text{ or } P_e}$$

where

$W_1$  = the flow of steam entering the turbine, including leakages, if any, lb/hr

$P_g$  = the net electrical output of turbine generator credited to the turbine under test, kw

$P_e$  = the output measured at the turbine coupling, kw

Sometimes guarantees are expressed as a steam rate without extraction for regenerative turbines designed for the extraction of steam for heating feed, type (c), in which case this rate will be calculated as for type (a), but during the test the extraction openings from the turbine must be closed. The closing-off of extraction steam to the heaters introduces a different operating condition from that contemplated in the purchase of the turbine. It is, therefore, desirable that guarantees for this type of turbine (c) be expressed in terms of heat rate or as an engine efficiency. (See Par. 294.)

## Heat Rates

**294.** For a complete expansion turbine, type (a), the performance may also be expressed as a heat rate, under stated operating conditions as to pressures, temperatures, output, etc.

$$\text{Heat rate, Btu per kw hr} = \frac{(W_1 - \Sigma W_g)(h_1 - h_{fz}) + \Sigma W_g(h_1 - h_{fz})}{P_g \text{ or } P_e}$$

in which

\*  $\Sigma W_g$  = the flow of steam measured in a leak-off pipe from glands, and from valve stems, etc., that receive steam from a point upstream of a reheater, which is led to waste or employed for any purpose extraneous to the turbine system under test and it or its heat is not delivered to any portion of the turbine steam or condensate path, and flow, if any, escaping to atmosphere.

$h_1$  = enthalpy of steam supplied.

$h_{fz}$  = enthalpy of saturated liquid at exhaust pressure.

\*  $h_{fz}$  = enthalpy of saturated liquid at the pressure of the extraneous leak-off steam from glands.

(Other symbols as in Par. 291.)

**296.** For a reheating turbine without feed heating, type (b), the heat rate under stated operating conditions as to pressures, temperatures, output, etc., is:

Heat rate, Btu per kw hr =

$$\frac{\{(W_1 - \Sigma W_g)h_1 - (W_1 - \Sigma W_g - \Sigma W_{gr})h_{fz} + (W_2 - \Sigma W_{gr})h_2 - W_2h_2\} + \Sigma W_g(h_1 - h_{fz}) + \Sigma W_{gr}(h_2 - h_{fz})}{P_g \text{ or } P_e}$$

in which

\*  $\Sigma W_{gr}$  = flow of extraneous leak-off steam from glands, etc., that receive steam from downstream of a reheater, lb/hr.

$W_2$  = flow of steam to the reheater, lb/hr.

$h_2$  = enthalpy of steam to reheater, Btu/lb.

$W_2$  = flow of steam from reheater, lb/hr.

$h_2$  = enthalpy of steam returned from reheater, Btu/lb.

(Other symbols as in Pars. 291 and 294.)

**297.** (a) For a regenerative turbine, i.e., one provided for extraction for heating its own feedwater but without reheating, type (c), under stated operating conditions as to

\* The subscript (g) designates "glands"; it is not to be confused with its standard significance (saturated vapor) which does not occur in this code.

pressures, temperatures, output, etc., the heat rate is, basically:

$$\text{Heat rate} = \frac{\text{Heat supplied} - \text{heat returned}}{\text{Output}}$$

which, expressed for a general case, is

$$\frac{W_1(h_1 - h_6)}{P_s \text{ or } P_c} \quad (1)$$

in which

$$W_1 = W_s.$$

$W_s$  = feedwater flow discharged from final heater, lb/hr.

$h_6$  = enthalpy of feedwater at discharge from final heater, Btu/lb.

(Other symbols as in Pars. 291, 294, and 296.)

(b) **Feed Pump.** Allowance shall be made in the heat rate formulas for the work and internal losses of a feed pump or pumps, if any, between the condenser and final feedwater heater. To accomplish this the value

$$+W_6(h_7 - h_6)$$

is added to the numerators of the heat rate formulas, where

$W_6$  = flow through feed pump, lb/hr.

$h_6$  = liquid enthalpy entering feed pump, Btu/lb.

$h_7$  = liquid enthalpy leaving feed pump, Btu/lb.

If two or more feed pumps are arranged to operate in series, between the condenser and final heater, an allowance for each of them shall be made.

Allowance for a condensate pump is not generally justified, because the enthalpy increase is negligible, unless the discharge pressure is more than 200 psi.

(c) **Make-up Feed and Allowance for Extraneous Leak-off Steam from Glands.** A regenerative turbine within a technical meaning of the words could not heat make-up feedwater. If water from an extraneous source (make-up feed) is heated by extracted steam, the turbine becomes, in part, an extraction turbine. For the turbine to be strictly regenerative,  $W_8$  must be equal to  $W_1$ . Certain leakages, however, such as  $\Sigma W_g$ , included in the measurement of  $W_1$ , do not reach the condenser or condensate system, and so are not included in the measurement of  $W_8$ .

For the turbine to be regarded as strictly regenerative, make-up feedwater equivalent to the weight of  $\Sigma W_g$  must be considered as being admitted to the system. Condenser leakage, if any, is to be considered as make-up feed. If steam jet air pumps are included in the turbine performance guarantees, their steam flow shall be considered as a part of the turbine steam flow. If not included in the guarantees, the condensate therefrom, if admitted to the condensate system, shall be considered as make-up feed, taken at the enthalpy of the condenser condensate.

For the turbine to be strictly regenerative, the following equation must be satisfied in the respect to make-up feed:

$$W_m + W_1 - \Sigma W_g = 0$$

in which

$W_m$  = make-up feedwater from an extraneous source, lb per hr.

$W_1$  = condenser leakage, including, if appropriate, condensate from steam jet air pumps, lb per hr.

(d) **Heat Rate.** If agreed by the parties to the test and if compatible with the contract or specification, the turbine may be regarded as strictly regenerative according to the foregoing item (c). If performance guarantees are based upon heating by extraction some quantity of make-up feed, not exceeding 5% of the initial flow, and/or it is impracticable to operate the plant without admitting make-up feed to the system, the guarantees and test result may be corrected to zero make-up feed, provided the make-up feed during the test does not exceed 5% of the initial steam flow.

(e) Any difference between  $W_8$  and  $W_1$  is to be considered in this case as make-up feed, either positive or negative, to be corrected to zero if the turbine is to be regarded as strictly regenerative.

(f) The code provides (see Par. 202[d]) that make-up feedwater shall, if practicable, be diverted elsewhere for the purpose of the test, in the case of the turbine being regarded as strictly regenerative.

(g) **Utilization Heat Rate.** Guarantees of performance of turbines, type (c) or (d), are frequently based upon considerable quantities of make-up feed being admitted to the con-

denser or condensate system and heated by extracted steam. If performance is to be determined under specified conditions as to make-up feed, the turbine becomes in part an extraction turbine. The term "heat rate" or "thermal efficiency" is not then applicable as a measure of performance.

If agreed by the parties to the test, and if compatible with the contract or specification, the performance may be expressed as a "utilization heat rate." This is the only permissible method of expressing performance when the specified quantity of make-up feed or that admitted during the test exceeds 5% of the initial steam flow.

(h) The complete formula for either the heat rate or the utilization heat rate, including allowances for extraneous leak-off steam from glands, etc., for make-up feedwater and for feed pump is:

$$\frac{(W_1 - \Sigma W_e)(h_1 - h_8) + W_e(h_7 - h_6) - W_e(h_8 - h_2) + \Sigma W_e(h_1 - h_{f2})}{P_g \text{ or } P_e} \quad (2)$$

where

$W_e$  = make-up feed flow, lb/hr.

$h_e$  = enthalpy of make-up feed, Btu/lb.

(Other symbols as above.)

(i) For the heat rate of a turbine regarded as strictly regenerative, corrections to the test result shall be made to render  $W_8 = W_1$ . In this case,  $W_e = W_m + W_t$  and is rendered numerically equal to  $\Sigma W_e$  and

$$h_e = \frac{W_m h_m + W_t h_t}{W_m + W_t}$$

(See items [c] and [f].)

The thermal efficiency of the strictly regenerative turbine may be taken as:

$$\frac{3412.7}{\text{Heat rate calculated according to foregoing items (h) and (i)}}$$

(j) For the utilization heat rate of a turbine regarded as not strictly regenerative, that is, the turbine heats by means of extraction some quantity of make-up feedwater, and  $W_8$  is greater than  $W_1$ , the following values will apply in the foregoing formula (2) of item (h):

$$W_8 = W_1 + W_e - \Sigma W_e$$

$$W_e = W_m + W_t$$

$$h_e = \frac{W_m h_m + W_t h_t}{W_m + W_t}$$

The utilization heat efficiency may be taken as:

$$\frac{3412.7}{\text{Utilization heat rate calculated according to foregoing items (h) and (j)}}$$

## SECTION 6. REPORT OF TESTS.

For standard form see the complete code.

## 6. TEST CODE FOR STEAM-CONDENSING APPARATUS

1. The term "steam-condensing apparatus" is intended to include all apparatus whose primary function is to reduce the exhaust pressure of a prime mover to a pressure below atmospheric and, in the case of surface condensers, to condense the steam so that the condensate is available for re-use as boiler feed.

### SECTION 1. OBJECT AND SCOPE.

4. The object of the test on steam-condensing apparatus shall be to verify the manufacturer's guarantees. The purpose of this code is to provide mandatory rules for determining the performance of a condenser with regard to one or more of the following:

The absolute pressure the apparatus will maintain at the steam inlet nozzle when transferring heat rejected by the prime mover at a given rate in Btu per hour with a given flow and temperature of circulating water, and a given tube cleanliness (see Sec. 5).

The thermal transmittance of surface condensers for given operating conditions noted in the preceding paragraph.

The amount of under-cooling of the condensate.

The percentage of dissolved oxygen in the condensate.

### SECTION 3. GUIDING PRINCIPLES.

67. The isolating of the steam and condensate circuits shall be accomplished by one of the following means: (a) Blank flanges. (b) Double valves with vent valves between. (c) Single gate valves with bonnet vent valves between the double disks.

68. **Air Leakage.** All packing glands on valve stems under vacuum on any part of the unit including those on the regenerative feedwater heaters, all piping joints on the prime mover, and all joints in the turbine or condenser casing shall be thoroughly inspected for possible air leaks. An agreement shall be reached and recorded in writing before test on the maximum amount of "free air" leakage, as measured during test, that will be tolerated by the parties to the test. In no case should tests be undertaken until the leakage has been reduced to less than 5 cu ft per min.

69. **Cooling Water Leakage.** Since the load on a surface condenser is a function of the steam condensed per hour which is determined by measuring the condensate, any cooling water leakage into the steam space of a surface condenser shall be determined prior to the start of the test. No test shall be undertaken with leakage in excess of the following percentages of the steam flow at the rated load capacity of the prime mover as deduced from performance guarantees.

#### Turbine rating:

Less than	500 kw	1.00%
	500 to 1000 kw	0.75%
	1000 to 5000 kw	0.50%
Above	5000 kw	500 lb per hr

80. **Frequency of Readings.** With a one-hour run, the cooling water temperatures should be taken every 2 1/2 min. Other readings should be taken every 5 minutes. If the duration of a test run is more than one hour the frequency of the water temperature readings may be reduced accordingly.

### SECTION 4. INSTRUMENTS AND METHODS OF MEASUREMENT.

85. **Condenser Pressure Measurement.** Mercury manometers, or by agreement absolute pressure gages, shall be used for measuring the condenser inlet pressure. The glass of these gages shall be high grade lead-free tubing, not smaller than 1/4 in. internal diameter, and preferably 1/2 in. at the point of measurement. The mercury used shall be clean and pure. The scales on the gages shall be divided into 0.02 in. divisions, but the smallest division may be 0.1 in. if the gages are equipped with verniers so that they can be readily read to 0.01 in. Either type of gage shall be carefully checked, and any error proved to be less than 0.01 in. Hg. Absolute pressure gages, if used, shall be checked at the beginning and end of the test by comparison with a mercury manometer and barometer.

87. The condenser inlet pressure shall be measured at or on either side of, but adjacent to, the joint connecting the turbine and condenser. If an approximately straight conduit connects the turbine exhaust to the condenser inlet the measurements shall be made near the condenser end of the conduit.

92. **Barometer.** The Fortin or Kew type of mercury-in-glass barometer shall be used exclusively for measuring the atmospheric pressure. The aneroid type of barometer is prohibited because of its unreliability, except where mercury-in-glass barometers are impractical, such as on shipboard during rough weather.

95. **Cooling Water Temperatures.** Mercury-in-glass thermometers with graduations etched on the stem shall be used for measuring the cooling water temperatures at inlet and outlet to the condenser water boxes. These thermometers shall be graduated in tenths or two-tenths of a degree and shall be accurate to within 0.1 F. The thermometers shall be inserted into oil-filled thermometer wells which project into the water conduits a distance above equal to 1/5 the conduit diameter. By agreement bare thermometers, suitably protected by wire cages, may be used. Also, by agreement properly calibrated resistance thermometers may be used.

97. **Condensate and Air Temperatures.** Mercury-in-glass thermometers, graduated in half degrees, shall be used for measuring the condensate temperature and the air outlet temperature. The spacing of the graduations on these thermometers shall be sufficiently wide to permit estimation to tenths of a degree and shall be accurate to within 0.5 F. Oil-filled thermometer wells shall be provided for the condensate thermometers. For measuring air outlet temperatures, insert the thermometers through rubber stoppers directly into the air stream.

98. Mercury-in-glass thermometers shall also be used for measuring the condensate (and raw water, if used) temperature entering and leaving air ejector condenser. These thermometers shall be graduated in half degrees, and shall be accurate to within 0.5 F.

**104. Condensate Flow-rate Measurement.** The condensate from the condenser shall be measured by one of the following means: (a) Tanks mounted on weighing scales. (b) Volumetric tanks. (c) Venturi tubes, nozzles, or orifice plates upon agreement of the parties to the test.

In all cases correction for condenser leakage shall be made.

**119. Dissolved oxygen** in the condensate shall be measured at the discharge of the condensate pump, first making sure no leaks exist at glands or casing joints of the pump. The Winkler method, as described in *Bulletin 151* of the United States Public Health Service, shall be followed in collecting, fixing, and titrating the sample. At least three samples shall be taken during each run. Only a chemist or someone trained specially for this work should attempt to determine the dissolved oxygen in the condensate.

#### SECTION 5. CLEANLINESS-FACTOR DETERMINATION.

**122. Definition of Cleanliness Factor.** Cleanliness factor, a term used to express the degree of tube fouling, is defined as the ratio of the thermal transmittance of the tubes whose cleanliness factors are being determined to that of new tubes, operating under identical conditions of circulating water temperature and velocity, and the same external steam temperature and flow. The overall cleanliness factor of a condenser is the average cleanliness factor of all the tubes, but because of test limitations it is necessary to determine this value from measurements on a limited number of tubes in representative positions.

**125. Procedure.** For the cleanliness-factor determination, the tubes selected for test shall be isolated and their thermal transmittances determined. The data required for each tube are: the outside area of tube, the enveloping vapor temperature, the inlet and outlet temperatures of the cooling water, and the rate of flow of the water. These readings shall be taken simultaneously with the overall test in order to eliminate any question of possible changes in the cleanliness factor between the time of making the cleanliness factor determination and the overall test. This procedure will give a cleanliness factor for each run and will eliminate any errors in interpolating where the cleanliness factor decreases during the test period. Where different water velocities are used the cleanliness will be different even though no fouling occurs during the test period.

**127. Selection of Sample Tubes.** Groups of four tubes each shall be selected by the parties to the test at such points in the condenser as will give an average of the service conditions for all tubes in the condenser. The location of each of the four tubes in each group shall be such that they will be subjected to, as nearly as possible, the same service conditions on the steam side as possible and they shall not be separated from each other by more than one intervening tube. The number of groups selected shall be not less than one per 2000 tubes and in no case less than four groups. The selected sample tubes shall be considered representative of the entire condenser as to cleanliness when the average heat transmittance of the sample tubes is within  $\pm 7\%$  of the value for the entire condenser, both computed on the same basis, i.e., using the steam temperature at the top of the condenser.

#### SECTION 7. STEAM JET AIR PUMPS.

**148.** Under actual operating conditions the vapor in the mixture removed from condensers is saturated and may even carry entrained moisture. The performance of steam-jet air pumps is affected materially by the moisture content of the air handled. Therefore, shop tests shall be made using air with its vapor saturated.

**149.** The performance of steam-jet air pumps depends upon:

- (a) The quantity and temperature of the mixture removed from the main condenser.
- (b) The steam pressure and temperature at the ejector nozzles.
- (c) The quantity and temperature of the cooling water passing through the ejector's intermediate and after condensers.

**151. Test Method.** In so far as is possible the pump shall be operated under the conditions specified in the contract. All adjustments shall be made prior to the test and maintained throughout the test period. The duration of each run is usually governed by the time required to secure the necessary readings. At least three sets of consecutive readings, which give approximately consistent data, shall be taken. Since all instruments used are of the indicating type there is no need for long test runs.

**152.** The quantity of air handled by the pump can be governed by the size of nozzle used in the air intake pipe. It is customary to treat the quantity of air handled as the independent variable and to determine the absolute pressure maintained for a range of flows.

**155.** A bare-bulb thermometer inserted into the air intake pipe through a rubber stopper shall be used for measuring the temperature of the air and vapor mixture as received by the pump.

**156.** The steam consumption of the pump shall be measured by using the ejector nozzles as the steam metering device.

**157.** The quantity of cooling water circulating through the intermediate and after condensers shall be measured with venturi tube, nozzle, or orifice plate.

**COMPUTATION AND REPORT OF RESULTS.**

Consult the complete code for data on this subject.

# NUMBERS

## 1. LOGARITHMS

**Logarithms** (abbreviation *log*).—The log of a number is the exponent of the power to which it is necessary to raise a fixed number to produce the given number. The fixed number is called the *base*. Thus if the base is 10, the log of 1000 is 3, for  $10^3 = 1000$ . There are two systems of logs in general use, the *common*, in which the base is 10, and the *Napierian*, or *hyperbolic*, in which the base is 2.718281828. . . . The Napierian base is commonly denoted by *e*, as in the equation  $e^y = x$ , in which *y* is the Napierian log of *x*. The abbreviation *log<sub>e</sub>* is commonly used to denote the Napierian log.

In any system of logs, the log of 1 is 0; the log of the base, taken in that system, is 1. In any system the base of which is greater than 1, the logs of all numbers greater than 1 are positive and the logs of all numbers less than 1 are negative.

The modulus of any system is equal to the reciprocal of the Napierian log of the base of that system. The modulus of the Napierian system is 1, that of the common system is 0.4342945. The log of a number in any system equals the modulus of that system  $\times$  Napierian log of the number. The *hyperbolic* or *Napierian* log of any number equals the common log  $\times$  2.3025851.

Every log consists of two parts, an integral part called the *characteristic*, or index, and the decimal part, or *mantissa*. The mantissa only is given in the usual tables of common logs, with the decimal point omitted. The characteristic is one less than the number of figures to the left of the decimal point in the number whose log is to be found. The characteristic of numbers from 1 to 9.99+ is 0, from 10 to 99.99+ is 1, from 100 to 999+ is 2, from 0.1 to 0.99+ is -1, from 0.01 to 0.099+ is -2, etc. Thus,

log of 2000 is	3.30103;	log of 0.2	is	-1.30103,	or	9.30103 - 10
" " 200 "	2.30103;	" " 0.02	"	-2.30103,	"	8.30103 - 10
" " 20 "	1.30103;	" " 0.002	"	-3.30103,	"	7.30103 - 10
" " 2 "	0.30103;	" " 0.0002	"	-4.30103,	"	6.30103 - 10

The minus sign is frequently written above the characteristic thus:  $\log 0.002 = \bar{3}.30103$ . The characteristic only is negative, the decimal part, or mantissa, being always positive.

When a log consists of a negative index and a positive mantissa, it is usual to write the negative sign over the index, or to add 10 to the index, and indicate the subtraction of 10 from the resulting logarithm. Thus  $\log 0.2 = 1.30103$ , may be written  $9.30103 - 10$ . The difference between a logarithm and 10 is its *arithmetical complement* or *cologarithm*.

In tables of logarithmic sines, etc., the -10 is generally omitted, as being understood.

**RULES FOR USE OF THE TABLE OF COMMON LOGARITHMS.**—To Find the Log of a Decimal Fraction or of a Whole Number and a Decimal.—First find the log of the quantity as if there were no decimal point, then prefix the index according to rule; the index is one less than the number of figures to the left of the decimal point.

**EXAMPLE.**  $\log$  of 3.14159.  $\log$  of 3.141 = 0.497068. Diff. = 138.

From proportional parts	5	=	690
" " "	09	=	1242
	<u>log 3.14159</u>		<u>0.4971494</u>

If the number is a decimal less than unity, the index is negative and is one more than the number of zeros to the right of the decimal point.  $\log$  of 0.0682 =  $\bar{2}.833784 = 8.833784 - 10$ .

**To Find the Number Corresponding to a Given Log.**—Find in the table the log nearest to the decimal part of the given log and take the first four digits of the required number from the column N and the top of the column containing the log which is the next less than the given log. To find the 5th and 6th digits subtract the log in the table from the given log, and multiply the difference by 100, and divide by the figure in the Diff. column opposite the log; annex the quotient to

the four digits already found, and place the decimal point according to the rule; the number of figures to the left of the decimal point is one greater than the index. The number corresponding to a log is called the anti-logarithm.

Find the anti-log of..... 0 497150  
 Next lowest log in table corresponds to 3141..... 0 497068      Diff. = 82.  
 Tabular diff. = 138;  $82 \div 138 = 0.59 +$

The index being 0, the number is therefore 3 14159+.

**Multiplication by Means of Logarithms.**—Add together the logs of the two numbers to be multiplied. The sum is the log of the product.

a. Where both factors are greater than unity.

EXAMPLE.  $31 \times 1274 = 39,494$ .

Solution.  $\log 31 + \log 1274 = 1.491362 + 3.105169 = 4.596531 = \log 39,494$ .

b. Where one or more factors are less than unity, the logs with a negative characteristic can be handled most conveniently by adding and subtracting 10.

EXAMPLE.  $.000028961 \times .084507 = .0000024474$

Solution.  $\log .000028961 + \log .084507 = \bar{5} 461814 + \bar{2} 926893$   
 $= (5 461814 - 10) + (8.926893 - 10) = 14 388707 - 20 = \bar{5} 388707$   
 $= \log .0000024474$ .

**Division by Means of Logarithms.**—Subtract the log of the divisor from the log of the dividend. The remainder is the log of the quotient.

a. When the divisor is smaller than the dividend.

EXAMPLE.  $2987 \div 63 = 47.41284$ .

Solution.  $\log 2987 - \log 63 = 3 475235 - 1.799341 = 1.675894 = \log 47 41284$ .

b. When the divisor is larger than the dividend, add and subtract as many tens as may be necessary to the log of the dividend and proceed as before.

EXAMPLE.  $.000672 \div 263 = .00000255513$ .

Solution.  $\log .000672 - \log 263 = \bar{4} 827369 - 2 419956$   
 $= 6.827369 - 2 419956 - 10 = \bar{4} 407413 = \log .00000255513$ .

c. The log of a fraction is obtained by subtracting the log of the denominator from the log of the numerator. Thus,

$$\log \frac{a}{b} = \log a - \log b.$$

**To Raise a Number to Any Given Power.**—Multiply the log of the number by the exponent of the number, and find the number whose log is the product.

a. Where the exponent consists of one figure.

EXAMPLE.  $16^2 = 42516528$

Solution.  $3 \times \log 16^2 = 3 \times 1 209515 = 3 628545 = \log 4251 528$ .

b. Where the exponent consists of two or more figures, it is best to multiply the characteristic and mantissa separately.

EXAMPLE.  $.005624^{.37} = .147067$ .

Solution.  $.37 \times \log .005624 = .37 \times \bar{5} 750045 = 37 \times (-3) + 37 \times 750045$   
 $= -111 + 277517 = \bar{1} 167517 = \log .147067$ .

c. Where the number is a fraction, first find the log of the fraction and then multiply it by the exponent.

EXAMPLE.  $\left(\frac{276}{.032}\right)^{.72} = 681.9396$ .

Solution.  $.72 (\log 276 - \log .032) = .72 \{ 2 440909 - (8.505150 - 10) \}$   
 $= .72 \times 3.935759 = 2.833746 = \log 681.9396$ .

**To Extract Any Root of a Number.**—Divide the log of the number by the index of the root, and find the number whose log is the quotient.

To extract the root of a decimal: a. When the root index is positive and evenly divisible into the negative characteristic of the log of the number, the division may be performed with the negative characteristic written in its usual place.

EXAMPLE.  $\sqrt[4]{.0006954} = .16239$ .

Solution.  $\log .0006954 \div 4 = 4 842235 \div 4 = \bar{1} 210559 = \log .16239$ .

b. When the root index is positive and not even divisible into the negative characteristic, add to the log of the number, and indicate the subtraction from it, the smallest integral multiple of the root which will eliminate the negative characteristic. Divide the result by the root index and ascertain the number whose log corresponds to the quotient.

EXAMPLE.  $\sqrt[3]{.00002785} = .03393$ .

Solution.  $\log .00002785 = \bar{5} 444825; \bar{5} 444825 \div 3.1 = \{(2 \times 3.1) + \bar{5} 444825 - 2 \times 3.1\} \div 3.1$   
 $= \{1.644825 - 6.2\} \div 3.1 = \bar{5} 530589 = \log .03393$ .

c. When the root index is negative, determine the excess of the negative characteristic over the positive mantissa. Divide the result by the root index and ascertain the number whose log corresponds to the quotient.

EXAMPLE.  $\sqrt[4]{.000003976} = 22.394$ .

Solution.  $\log .000003976 = \bar{5} 599446 - 6 = -5.400554$   
 $= -5.400554 \div (-4) = 1.350138 = \log 22.394$ .

**Solution of Exponential Equations.**—In an exponential equation, the unknown quantity is the exponent; thus  $a^x = b$ . This may be transformed to  $\log a^x = \log b$ , or  $x \log a = \log b$ , whence  $x = \log b \div \log a$ .

a. When the base is greater than unity, put the equation in the form  $x = \log b \div \log a$ . Then  $\log x = \log (\log b) - \log (\log a)$ .

EXAMPLE.  $32.6^x = 14.832$ .

Solution.  $\log x = \log (\log 14.832) - \log (\log 32.6) = \log 1.165303 - \log 1.513218$   
 $= .066439 - .179901 = \bar{1}.886538; x = .77008$ .

b. When both the known quantities are decimal, put the equation in the form  $x = \log b \div \log a$ . Subtract the positive mantissa from the negative characteristic in both divisor and dividend, obtaining negative remainders. Change the signs of divisor and dividend and proceed as in Case a.

EXAMPLE.  $.0729^x = .2693$ .

Solution.  $x = \log .2693 \div \log .0729 = \bar{1}.430236 \div \bar{1}.862728$   
 $= (-.569764) \div (-1.137272) = .569764 \div 1.137272;$   
 $\log x = \log .569764 - \log 1.137272 = \bar{1}.755695 - .055864 = \bar{1}.699831$   
 $x = .50099$ .

c. When only one of the known quantities is a decimal, put the equation in the form  $x = \frac{\log b}{\log a}$ .

Subtract the positive mantissa from the negative characteristic of the numerator or denominator as the case may be, and rewrite the fraction with the remainder so obtained as the new numerator or denominator. Make both numerator and denominator positive, but write a minus sign in front of the fraction, to signify that the result will be a negative quantity. Solve the fraction by logarithms and write a minus sign in front of the result.

EXAMPLE.  $.726^x = 802.7$ .

Solution.  $x = \frac{\log 802.7}{\log .726} = \frac{2.904553}{\bar{1}.860937} = -\frac{2.904553}{.139063}$   
 $\log x = -(\log 2.904553 - \log .139063) = -(.463079 - \bar{1}.143211) = -(1.319868).$   
 $x = -20.8867$ .

d. When the exponent is negative and one of the known quantities is less than unity, put the equation in the form  $(-x) = \frac{\log b}{\log a}$ . Subtract the positive mantissa from the negative characteristic, as in Case c, and multiply both sides of the resulting equation by  $(-1)$ . Find the value of  $x$  as in Case c.

EXAMPLE.  $10.78^{-x} = .09431$ .

Solution.  $x = \frac{\log .09431}{\log 10.78} = \frac{\bar{1}.974558}{1.032619}; x = \frac{1.025442}{1.032619}$   
 $\log x = .010911 - .013940 = \bar{1}.996971. x = .99305$ .

Table 3. Natural (Napierian or Hyperbolic) Logarithms of Numbers

Table gives natural logarithms of numbers from 1.0 to 9.90 directly. To find logarithms of numbers outside that range add or subtract natural logarithm of the powers of 10 as follows:

$$\begin{aligned} \log_e 10 &= 2.302585 & \log_e 10^4 &= 9.210340 & \log_e 10^7 &= 16.118006 \\ \log_e 10^2 &= 4.605170 & \log_e 10^5 &= 11.512925 & \log_e 10^8 &= 18.420681 \\ \log_e 10^3 &= 6.907755 & \log_e 10^6 &= 13.815511 & \log_e 10^9 &= 20.703266 \end{aligned}$$

EXAMPLE.— $\log_e 679 = \log_e 6.79 + \log_e 10^2 = 1.9155 + 4.6052 = 6.5207$

$$\log_e .0679 = \log_e 6.79 - \log_e 10^2 = 1.9155 - 4.6052 = -2.6897$$

The common logarithm is the natural logarithm multiplied by the modulus of  $\log_{10}$ ;  $\log_{10} N = 0.434294 \log_e N$ .

**Table 4. Values and Logarithms of Exponentials and Hyperbolic Functions**

The following tables give values of  $e^x$ ,  $e^{-x}$ ,  $\sinh x$ ,  $\cosh x$  and  $\tanh x$  for values of  $x$  from 0.00 to 6.00 in intervals of 0.01.

To facilitate computations involving multiplication, the common logarithms of  $e^x$ ,  $\sinh x$ ,  $\cosh x$ , and  $\tanh x$  are also given.

For values of  $x$  greater than 6:  $e^x$  may be computed from the relationship  $e^x = \log^{-1}(x \log_{10} e) = \log^{-1} 0.43429x$ ;  $e^{-x}$  approaches zero;  $\sinh x$  and  $\cosh x$  are approximately equal and become  $0.5 e^x$ ; and  $\tanh x$  and  $\coth x$  have values approximately equal to unity.

Where more accurate values of the exponentials and functions are required they may be computed from the following relationships.

$$e = 2.71828\ 18285$$

$$\frac{1}{e} = 0.36787\ 94412$$

$$M = \log_{10} e = 0.43429\ 44819$$

$$\frac{1}{M} = \log_e 10 = 2.30258\ 50930$$

$$e^x = \log^{-1} Mx$$

$$= \log^{-1} - Mx$$

$$\sinh x = \frac{e^x - e^{-x}}{2}$$

$$\cosh x = \frac{e^x + e^{-x}}{2}$$

$$\tanh x = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\operatorname{csch} x = \frac{1}{\sinh x}$$

$$\operatorname{sech} x = \frac{1}{\cosh x}$$

$$\coth x = \frac{1}{\tanh x}$$

**Chart of the Hyperbolic Functions.**

## 3. MEASURES, WEIGHTS, AND UNITS

Flow and capacity equivalents, Tables 8 and 9, are based on the following values.

1 cubic foot = 7.480519 U. S. gallons

1 U. S. gallon = 231 cu in = 0.13368056 cu ft

1 lb of water at 62° F = 0.01603489 cu ft

The British Imperial gallon = 277.418 cu in (U.S.) = 277.420 cu in (British) = 1.20094 U. S. gallons.

The flow equivalents of Table 8 are based on water at 62° F. These flow equivalents for a given weight of water can be converted to flow equivalents for any other fluid by multiplying by the ratio of the density of that fluid to the density of water. For example the flow per minute of 20 lb of oil of specific gravity 0.90 (water = 1.0) is]

$$(1/0.90) \times 20 \times 0.1200 = 2.67 \text{ gal. per min.}$$

Table 8. Flow Equivalents

	Cu. ft. per sec.	Cu. ft. per min.	U. S. Gallons per min.	U. S. Gals. per hr.	U. S. Gallons per 24 hr.	Lb. H <sub>2</sub> O per min.	Lb. H <sub>2</sub> O per hr.

## MEASURES AND WEIGHTS COMMONLY USED IN THE UNITED STATES AND GREAT BRITAIN

## Abbreviations

bbl.	= barrel	dwt.	= pennyweight	hr.	= hour	quin.	= quintal
bu.	= bushel	fath.	= fathom	imp.	= Imperial (bu., gal.)	qr.	= quarter
chn.	= chain	ft.	= foot	in.	= inch	qt.	= quart
circm.	= circumference	fl. drn.	= fluid drachm	lea	= league	scr.	= scruple
cir. in.	= circular inch	fl. oz.	= fluid ounce	m. pace	= military pace	sec.	= second
cir. mil.	= circular mil	furl.	= furlong	min.	= minute	sq.	= square (in., ft., etc.)
cwt.	= hundred weight	gal.	= gallon (U.S.)	naut. mi.	= nautical mile	stat. mi.	= statute mile
deg.	= degree	grn.	= grain	pnech	= puncheon	tree.	= tierce
drm.	= drachm (dram)	hghd.	= hoghead	quad.	= quadrant	yd.	= yard

Table 10. Measures of Length

Long Measure	
12 in.	= 1 ft.
3 ft.	= 1 yd.
5 1/2 yd.	= 16 1/2 ft. = 1 rod, pole or perch
40 poles	= 220 yd. = 1 furl.
8 furl.	= 1760 yd. = 5280 ft. = 1 mile
4 in.	= 1 hand
9 in.	= 1 span
2 1/2 ft.	= 1 m. pace.

## Land, Surveyors, or Gunter's Measure

7.92 in.	= 1 link
100 links	= 66 ft. = 4 rods = 1 chn.
10 chn.	= 220 yd. = 1 furl.
8 furl.	= 80 chn. = 1 mile.

## Nautical Measure

6080.26 ft.	= 1.15156 stat. mi. = 1 naut. mi.
3 naut. mi.	= 1 lea.
60 naut. mi.	= 1 deg. (at equator)
6 ft.	= 1 fath.
120 fath.	= 1 cable
1 naut. mi. per hr.	= 1 knot.

Table 11. Measures of Area

Square Measure	
144 sq. in.	= 183 35 cir. in. = 1 sq. ft.
9 sq. ft.	= 1 sq. yd.
30 1/4 sq. yd.	= 272 1/4 sq. ft. = 1 sq. rod
160 sq. rods	= 10 chn.
4840 sq. yd.	= 43560 sq. ft. } = 1 acre
640 acres	= 27,878,400 sq. ft. = 1 sq. mile
1 acre	= (208.71 ft) <sup>2</sup>
1 cir. in.	= { area of circle 1 in. diam.
	= 0.7854 sq. in.
1 cir. mil	= { area of circle 0.001 in. diam.
	= 0.0007854 sq. in.
1,000,000 cir. mil	= 1 cir. in.

## Board Measure

144 cu. in. = 12 × 12 × 1 in. = 1 board ft.  
The above definition of a board foot applies to rough green lumber. American practice uses a yard standard of 29/32 in. thick and an industrial standard of 7/8 in. thick for rough dry lumber; for dressed lumber the corresponding thicknesses are 25/32 in. and 13/16 in. For example, a rough dry piece 12 × 12 × 29/32 in. contains 1 board ft. Board ft. in round timber = (1/4 c × d × l) / 144. c = mean circm., d = diam., l = length, all in ft.

Table 12. Measures of Weight

(The grain is the same in all systems.)

Avoirdupois Weight	
16 drn.	= 437.5 grn. = 1 oz.
16 oz.	= 7000 grn. = 1 lb.
14 lb.	= 1 stone
28 lb.	= 2 stone = 1 qr.
100 lb.	= 1 quin.
4 qr.	= 112 lb. = 1 cwt.
20 cwt.	= 2240 lb. = 1 long ton
2000 lb.	= 1 short ton.

## Troy Weight (for gold and silver)

24 grn.	= 1 dwt.
20 dwt.	= 480 grn. = 1 oz.
12 oz.	= 5760 grn. = 1 lb.
1 Assay ton	= 29,167 milligrams
	= { Troy oz. per 2000 lb.
	ton avoirdupois

## Carat Weight (for precious stones)

1 carat = 3.086 grn. = 0.200 gram

## Apothecaries' Weight

20 grn.	= 1 scr. ☉
3 scr.	= 60 grn. = 1 drn. 5
8 drn.	= 480 grn. = 1 oz. 5
12 oz.	= 5760 grn. = 1 lb.

Table 13. Measures of Volume

## Cubic Measure

1728 cu. in.	= 1 cu. ft.
27 cu. ft.	= 1 cu. yd.
1 cord of wood	= { 4 × 4 × 8 ft.
	= 128 cu. ft.
1 perch masonry	= { 16 1/2 × 1 1/2 × 1 ft.
	= 23 3/4 cu. ft.

## Liquid Measure

4 gills	= 1 pint
2 pints	= 1 qt.
4 qt.	= 231 cu. in. = 8.3356 lb. H <sub>2</sub> O
	= 1 U. S. gal.
	= 0.8327 Imp. gal.
1 Imp. gal.	= 277.420 cu. in.
	= 10 lb. H <sub>2</sub> O
1.20094 U. S. gal.	= 1 Imp. gal.
7.4805 U. S. gal.	= 1 cu. ft.

## Old Liquid Measure

31 1/2 gal.	= 1 bbl.
42 gal.	= 1 tree.
2 bbl.	= 63 gal. = 1 hghd.
84 gal.	= 2 tree = 1 pohn.
2 hghd.	= 126 gal. = 1 pipe or butt
2 pipes	= 3 pohn. = 1 tun.

## Apothecaries' Fluid Measure

60 minims	= 1 fl. drn.
8 drn.	= 1 fl. oz.
1 fl. oz.	= 1/128 U. S. gal. = 1.8047
	cu. in. = 456.3 grn. H <sub>2</sub> O
	at 39° F.
16 fl. oz.	= 1 pint
1 fl. oz. (British)	= 1.732 cu. in.
	= 437.5 grn. H <sub>2</sub> O at 62° F.

## Dry Measure

2 pints	= 1 qt.
8 qts.	= 1 peck
4 pecks	= 2150.42 cu. in.
	= 1 bu. (struck)
1 1/4 bu. (struck)	= 1 bu. (heaped)
105 qts. (struck)	= 7056 cu. in. = 1 bbl.
8 Imp. gal.	= 2218.192 cu. in.
	= 1 Imp. bu.
8 Imp. bu.	= 1 qr.

## Shipping Measure

100 cu. ft.	= 1 Register ton *
40 cu. ft.	= 31.143 U. S. bu.
	= 1 shipping ton (U. S.) †
42 cu. ft.	= 32.719 Imp. bu.
	= 1 shipping ton (British) †

\* For measurement of entire internal capacity  
† For measurement of cargo.

## Miner's Inch

A variable unit, defined by statute in different states as the quantity of water that will flow through an orifice of 1 sq. in. area, under a head ranging from 4 1/2 to 6 in. U. S. Reclamation Service defines the miner's inch as 1 cu. in. per sec. The law governing the locality in which the measurement is to be made should be consulted.

Table 14. Circular Measure

60 sec.	= 1 min.
60 min.	= 1 deg.
90 deg.	= 1 quad.
360 deg.	= 1 circ.
57.2957795 deg.	= 1 radian
	= 57° 17' 44.806"
1 radian	= angle of arc equal to radius.

Table 15. Time

60 sec.	= 1 min.	7 days	= 1 week
60 min.	= 1 hr.	52 weeks	= 1 year
24 hr.	= 1 day		
1 year (exact)	= 365 days, 5 hr., 48 min., 45.6 sec.		
A year divisible by 4 is a leap year and contains 366 days, except centesimal years, of which only those divisible by 400 are leap years.			
365.24734 mean solar days	= 366.008515 sidereal days		
24 hr. mean solar time	= 23 hr. 56 min., 49.9 sec. sidereal time		
1 mean solar day	= 1 mean sidereal day + 3 min., 10.1 sec.		

## THE METRIC SYSTEM

The fundamental standard of length in the metric system is the International Standard Meter, derived from the Metre des Archives, Paris. Its length is defined as the distance between two lines at 0° C. on a platinum-iridium bar deposited at the International Bureau of Weights and Measures near Paris. 1 meter = 39.37 in.

The fundamental standard of mass is the International Standard Kilogram, which is a mass of platinum-iridium, deposited at the International Bureau, whose weight *in vacuo* is the same as that of the Kilogram des Archives.

The fundamental unit of volume is the liter, which is defined as the volume of a kilogram of water at the temperature of maximum density, 4° C., under a pressure of 76 cm. of mercury. The liter originally was defined as a cubic decimeter, but is slightly greater. The generally accepted relation between the cubic decimeter and the liter is 1 liter = 1.000027 cu. decimeters.

The unit of force is the dyne, which is the force which acting for 1 second on a mass of one gram will produce a velocity of 1 centimeter per second. 1 dyne = (1/980 665) gram. 1,000,000 dynes = 1.020 kilograms force = 2.248 lb. force. 1 lb. force = 0.4536 kilogram force = 448,800 dynes.

The unit of heat is the gram-calorie, which is the quantity of heat required to raise 1 gram of water 1° C. See Section 3.

Table 16. Units of Metric Measures \*

Length			Area		
Unit	Symbol	Value in Meters	Unit	Symbol	Value in Sq. Meters
Micron	$\mu$	0.000 001	Sq. millimeter	sq. mm.	0.000 001

\* Area of segment of any radius = factor G X square of radius

Table 27. Areas of Segments of a Circle

Area =  $F \times D^2$  where segment < semicircle; =  $\frac{1}{4}\pi D^2 - (\text{area of segment of rise } h)$ .  $H$  = rise or height of segment;  $D$  = diam. of circle;  $F$  = factor corresponding to  $H/D$ .  $h = (D - H)$

## 5. MENSURATION

**Table 32a. Plane Rectilinear Figures**

**Notation:** Lines,  $a, b, c, \dots$ ; angles,  $\alpha, \beta, \gamma, \dots$ ; altitude (perpendicular height),  $h$ ; side,  $s$ ; diagonals,  $d, d_1, \dots$ ; perimeter,  $p$ ; radius of inscribed circle,  $r$ ; radius of circumscribed circle,  $R$ ; area,  $A$ .

### 1. Right Triangle

(One angle  $90^\circ$ )

$$p = a + b + c; c^2 = a^2 + b^2;$$

$$A = \frac{ab}{2} = \frac{a^2}{2} \tan \beta = \frac{c^2 \sin 2\beta}{4} = \frac{c^2 \sin 2\alpha}{4}.$$

For additional formulas, see *General Triangle* below, and also trigonometry.

### 2. General Triangle (and Equilateral Triangle)

*For General Triangle:*

$$p = a + b + c. \text{ Let } s = \frac{1}{2}(a + b + c).$$

$$r = \frac{\sqrt{s(s-a)(s-b)(s-c)}}{s}; R = \frac{a}{2 \sin \alpha} = \frac{abc}{4rs};$$

$$A = \frac{ah}{2} = \frac{ab}{2} \sin \gamma = \frac{b^2 \sin \gamma \sin \alpha}{2 \sin \beta} = rs = \frac{abc}{4R}.$$

$$\text{Length of median to side } c = \frac{1}{2} \sqrt{2(a^2 + b^2) - c^2}.$$

$$\text{Length of bisector of angle } \gamma = \frac{\sqrt{ab[(a+b)^2 - c^2]}}{a+b}.$$

*For Equilateral Triangle* ( $a = b = c = s$  and  $\alpha = \beta = \gamma = 60^\circ$ ):

(Equal sides and equal angles)

$$p = 3s; r = \frac{s}{2\sqrt{3}}; R = \frac{s}{\sqrt{3}} = 2r;$$

$$h = \frac{s\sqrt{3}}{2}; s = \frac{2h}{\sqrt{3}}; A = \frac{s^2\sqrt{3}}{4}.$$

For additional formulas, see trigonometry.

### 3. Rectangle (and Square)

*For Rectangle:*

$$p = 2(a + b); d = \sqrt{a^2 + b^2}; A = ab.$$

*For Square* ( $a = b = s$ ):

$$p = 4s; d = s\sqrt{2}; s = \frac{d}{\sqrt{2}}; A = s^2 = \frac{d^2}{2}.$$

### 4. General Parallelogram (Rhomboid) (and Rhombus)

*For General Parallelogram (Rhomboid):*

(Opposite sides parallel)

$$p = 2(a + b); d_1 = \sqrt{a^2 + b^2 - 2ab \cos \gamma};$$

$$d_2 = \sqrt{a^2 + b^2 + 2ab \cos \gamma}; d_1^2 + d_2^2 = 2(a^2 + b^2);$$

$$A = ah = ab \sin \gamma.$$

*For Rhombus* ( $a = b = s$ ):

(Opposite sides parallel and all sides equal)

$$p = 4s; d_1 = 2s \sin \frac{\gamma}{2}; d_2 = 2s \cos \frac{\gamma}{2}; d_1^2 + d_2^2 = 4s^2;$$

$$d_1 d_2 = 2s^2 \sin \gamma; A = sh = s^2 \sin \gamma = \frac{d_1 d_2}{2}.$$

### 5. General Trapezoid (and Isosceles Trapezoid)

Let mid-line bisecting non-parallel sides =  $m$ . Then  $m = \frac{a+b}{2}$ .

*For General Trapezoid:*

(Only one pair of opposite sides parallel)

$$p = a + b + c + d; A = \frac{(a+b)h}{2} = mh.$$

*For Isosceles Trapezoid* ( $d = c$ ):

(Non-parallel sides equal)

$$A = \frac{(a+b)h}{2} = mh = \frac{(a+b)c \sin \gamma}{2}$$

$$= (a - c \cos \gamma) c \sin \gamma = (b + c \cos \gamma) c \sin \gamma.$$

Table 32a. Plane Rectilinear Figures—Continued

6. General Quadrilateral  
(Trapezium)

(No sides parallel)

$$p = a + b + c + d$$

 $A = \frac{1}{2} d_1 d_2 \sin \alpha$  = sum of areas of the two triangles formed by either diagonal and the four sides.
7. Quadrilateral Inscribed  
in Circle(Sum of opposite angles =  $180^\circ$ )

$$ac + bd = d_1 d_2.$$

 $\text{Let } s = \frac{1}{2}(a + b + c + d) = \frac{p}{2} \text{ and } \alpha = \text{angle between sides } a \text{ and } b.$ 

$$A = \sqrt{(s-a)(s-b)(s-c)(s-d)} = \frac{1}{2}(ab + cd) \sin \alpha.$$

8. Regular Polygon (and  
General Polygon)*For Regular Polygon:*

(Equal sides and equal angles)

Let  $n$  = number of sides.

$$\text{Central angle} = 2\alpha = \frac{2\pi}{n} \text{ radians;}$$

$$\text{Vertex angle} = \beta = \frac{(n-2)}{n} \pi \text{ radians.}$$

$$p = ns; s = 2r \tan \alpha = 2R \sin \alpha;$$

$$r = \frac{s}{2} \cot \alpha; R = \frac{s}{2} \csc \alpha;$$

$$A = \frac{nsr}{2} = nr^2 \tan \alpha = \frac{nR^2}{2} \sin 2\alpha = \frac{ns^2}{4} \cot \alpha = \text{sum of areas of the } n \text{ equal triangles such as } OAB.$$

*For General Polygon:*
 $A$  = sum of areas of constituent triangles into which it can be divided

Table 32b. Plane Curvilinear Figures

**Notation.** Lines,  $a, b, \dots$ ; radius,  $r$ ; diameter,  $d$ ; perimeter,  $p$ ; circumference,  $c$ ; central angle in radians,  $\theta$ ; arc,  $s$ ; chord of arc ( $s$ ),  $l$ ; chord of half arc ( $s/2$ ),  $l'$ ; rise,  $h$ ; area,  $A$ .

9. Circle (and Circular Arc) *For Circle:*

$$d = 2r; c = 2\pi r = \pi d; A = \pi r^2 = \frac{\pi d^2}{4} = \frac{c^2}{4\pi}.$$

*For Circular Arc:*
 $\text{Let arc } PAQ = s; \text{ and chord } PA = \left(\text{chord of } \frac{s}{2}\right) = l'. \text{ Then,}$ 
 $s = r\theta = \frac{d\theta}{2}; s = \frac{8l' - l}{3}.$  (The latter equation is Huyghen's approximate formula. For  $\theta$  small, error is very small; for  $\theta = 120^\circ$ , error equals about 1 part in 400; for  $\theta = 180^\circ$ , error is less than 1.25%.)

$$l = 2r \sin \frac{\theta}{2}; l = 2 \sqrt{2hr - h^2} \quad (\text{approximate formula})$$

$$r = \frac{4h^2 + l^2}{8h} \quad (\text{approximate formula})$$

$$h = r \mp \sqrt{r^2 - \frac{l^2}{4}} \quad \left( \text{if } \theta \leq 180^\circ; + \text{ if } \theta \geq 180^\circ \right) = r \left( 1 - \cos \frac{\theta}{2} \right)$$

$$= r \operatorname{versin} \frac{\theta}{2} = 2r \sin^2 \frac{\theta}{4} = \frac{l}{2} \tan \frac{\theta}{4} = r + y - \sqrt{r^2 - x^2}.$$

Side ordinate  $y = h - r + \sqrt{r^2 - x^2}.$ 

Table 32b. Plane Curvilinear Figures—Continued

10. Circular Sector (and Semicircle)

For Circular Sector:

$$A = \frac{\theta r^2}{2} = \frac{\pi r^2}{2}$$

For Semicircle:

$$A = \pi r^2$$

11. Circular Segment

$$A = \frac{r^2}{2} (\theta - \sin \theta)$$

$$= \frac{1}{2} [sr \mp l (r - h)] \quad (- \text{if } h \leq r; + \text{if } h \geq r).$$

$$A = \frac{2lh}{3} \text{ or } \frac{h}{15} (8l' + 6l). \quad (\text{Approximate formulas. For } h \text{ small compared with } r, \text{ error is very small; for } h = \frac{r}{4}, \text{ first formula errs about 3.5\% and second } | \text{ than 1.0\%}).$$

12. Annulus

(Surface between two concentric circles)

$$A = \pi (r_1^2 - r_2^2) = \pi (r_1 + r_2) (r_1 - r_2);$$

$$A \text{ of sector } ABCD = \frac{\theta}{2} (r_1^2 - r_2^2) = \frac{\theta}{2} (r_1 + r_2) (r_1 - r_2) = \frac{\theta}{2} (s_1 + s_2).$$

13. Ellipse

$$p = \pi (a + b) \left( 1 + \frac{R^2}{4} + \frac{R^4}{64} + \frac{R^6}{256} + \dots \right) \text{ where } R = \frac{a-b}{a+b}.$$

$$p = \pi (a + b) \frac{64 - 3R^4}{64 - 16R^2} \quad (\text{approximate formula}).$$

$$A = \pi ab; \quad A \text{ of quadrant } AOB = \frac{\pi ab}{4}.$$

$$A \text{ of sector } AOP = \frac{ab}{2} \cos^{-1} \frac{x}{a}; \quad A \text{ of sector } POB = \frac{ab}{2} \sin^{-1} \frac{x}{a};$$

$$A \text{ of section } BPP'B' = xy + ab \sin^{-1} \frac{x}{a};$$

$$A \text{ of segment } PAP'P' = -xy + ab \cos^{-1} \frac{x}{a}.$$

For additional formulas, see analytic geometry.

14. Parabola

$$\text{Arc } BOC = s = \frac{1}{2} \sqrt{l^2 + 16h^2} + \frac{l^2}{8h} \log_e \frac{4h + \sqrt{l^2 + 16h^2}}{l}.$$

$$\text{Let } R = \frac{h}{l}. \text{ Then,}$$

$$s = l \left( 1 + \frac{8R^2}{3} - \frac{32R^4}{5} + \dots \right) \quad (\text{approximate formula}).$$

$$d = \frac{h}{l^2} (l^2 - l_1^2); \quad l_1 = l \sqrt{\frac{h-d}{h}}; \quad h = \frac{dl^2}{l^2 - l_1^2};$$

$$A \text{ of segment } BOC = \frac{2hl}{3};$$

$$A \text{ of section } ABCD = \frac{2}{3} d \left( \frac{l^2 - l_1^2}{l^2 - l_1^2} \right).$$

For additional formulas, see analytic geometry.

15. Hyperbola

$$A \text{ of figure } OPAP'O = ab \log_e \left( \frac{x}{a} + \frac{y}{b} \right) = ab \cosh^{-1} \frac{x}{a};$$

$$A \text{ of segment } PAP' = xy - ab \log_e \left( \frac{x}{a} + \frac{y}{b} \right) = xy - ab \cosh^{-1} \frac{x}{a}.$$

For additional formulas, see analytic geometry.

Table 32b. Plane Curvilinear Figures—Continued

## 16. Cycloid

cycloid

$$\text{Arc } OP = s = 4r \left(1 - \cos \frac{\phi}{2}\right); \text{ Arc } OMN = 8r;$$

$$A \text{ under curve } OMN = 3\pi r^2.$$

For additional formulas, see analytic geometry.

## 17. Epicycloid

Epicycloid

$$\text{Arc } MP = s = \frac{4r}{R} (R+r) \left(1 - \cos \frac{R\phi}{2r}\right);$$

$$\text{Area } MOP = A = \frac{r}{2R} (R+r)(R+2r) \left(\frac{R\phi}{r} - \sin \frac{R\phi}{r}\right).$$

For additional formulas, see analytic geometry.

## 18. Hypocycloid

Hypocycloid

$$\text{Arc } MP = s = \frac{4r}{R} (R-r) \left(1 - \cos \frac{R\phi}{2r}\right);$$

$$\text{Area } MOP = A = \frac{r}{2R} (R-r)(R-2r) \left(\frac{R\phi}{r} - \sin \frac{R\phi}{r}\right).$$

For additional formulas, see analytic geometry.

## 19. Catenary

If  $d$  is small compared with  $l$ :

$$\text{Arc } MPN = s = l \left[1 + \frac{2}{3} \left(\frac{2d}{l}\right)^2\right] \text{ (approximately).}$$

For additional formulas, see analytic geometry.

## 20. Helix

Let length of helix =  $s$ ; radius of coil (= radius of cylinder in figure) =  $r$ ; distance advanced in one revolution = pitch =  $h$ ; and number of revolutions =  $n$ . Then,

## 21. Spiral of Archimedes

Let  $a = \frac{r}{\phi}$ . Then,

$$\text{Arc } OP = s = \frac{a}{2} \left[\phi \sqrt{1 + \phi^2} + \log_e \left(\phi + \sqrt{1 + \phi^2}\right)\right].$$

For additional formulas, see analytic geometry.

## 22. Irregular Figure

Divide the figure into an even number,  $n$ , of strips by means of  $(n+1)$  ordinates,  $y_i$ , spaced equal distances,  $w$ . The area can then be determined approximately by any of the following formulas, which are presented in the order of usual increasing approach to accuracy. In any of the first three cases, the greater the number of strips used, the more nearly accurate will be the result.

(Approximate Formulas)

Trapezoidal Rule....

$$A = w \left[ \frac{y_0 + y_n}{2} + y_1 + y_2 + \dots + y_{n-1} \right];$$

Durand's Rule.....

$$A = w [0.4(y_0 + y_n) + 1.1(y_1 + y_{n-1}) + y_2 + y_3 + \dots + y_{n-2}];$$

Simpson's Rule.....  
( $n$  must be even)

$$A = \frac{w}{3} [(y_0 + y_n) + 4(y_1 + y_3 + \dots + y_{n-1}) + 2(y_2 + y_4 + \dots + y_{n-2})];$$

Weddle's Rule.....  
(for 6 strips only)

$$A = \frac{3w}{10} [5(y_1 + y_5) + 6(y_3 + y_0 + y_2 + y_4 + y_6)].$$

Areas of irregular surfaces can often be determined more quickly by such methods as plotting on squared paper and counting the squares; graphical coordinate representation (see analytic geometry); or use of a planimeter.

Table 32c. Solids Having Plane Surfaces

**Notation.** Lines,  $a, b, c, \dots$ ; altitude (perpendicular height),  $h$ ; slant height,  $s$ ; perimeter of base,  $p_b$  or  $p_B$ ; perimeter of a right section,  $p_r$ ; area of base,  $A_b$  or  $A_B$ ; area of a right section,  $A_r$ ; total area of lateral surfaces,  $A_l$ ; total area of all surfaces,  $A_t$ ; volume,  $V$ .

**23. Wedge (and Right Triangular Prism)**

For Wedge:

$$(\text{Narrow-side rectangular}); V = \frac{ab}{6} (2l_1 + l_2).$$

For Right Triangular Prism (or wedge having parallel triangular bases perpendicular to sides)  $l_2 = l_1 = l$ :

$$V = \frac{abl}{2}.$$

**24. Rectangular Prism (or Rectangular Parallelepiped) (and Cube)**

For Rectangular Prism or Rectangular Parallelepiped:

$$A_l = 2c(a + b); A_t = 2(de + ac + bc);$$

$$V = A_r c = abc.$$

For Cube (letting  $b = c = a$ ):

$$A_t = 6a^2; V = a^3; \text{Diagonal} = a\sqrt{3}.$$

**25. General Prism**

$$A_l = hp_b = sp_r = s(a + b + \dots + n);$$

$$V = hA_b = sA_r.$$

**26. General Truncated Prism (and Truncated Triangular Prism)**

For General Truncated Prism:

$$V = A_r \cdot (\text{length of line } BC \text{ joining centers of gravity of bases}).$$

For Truncated Triangular Prism:

$$V = \frac{A_r}{3} (a + b + c).$$

**27. Prismatoid**

Let area of mid-section =  $A_m$ .

$$V = \frac{h}{6} (AB + AB' + 4A_m).$$

**28. Right Regular Pyramid (and Frustum of Right Regular Pyramid)**

For Right Regular Pyramid:

$$A_l = \frac{sp_B}{2}; V = \frac{hA_B}{3}.$$

For Frustum of Right Regular Pyramid:

$$A_l = \frac{s}{2} (p_B + p_b); V = \frac{h}{3} (AB + Ab + \sqrt{ABAb}).$$

**29. General Pyramid (and Frustum of Pyramid)**

For General Pyramid:

$$V = \frac{hA_B}{3}.$$

For Frustum of General Pyramid:

$$V = \frac{h}{3} (AB + Ab + \sqrt{ABAb}).$$

**30. Regular Polyhedrons**

Tetrahedron Cube Octahedron

Dodecahedron Icosahedron

Let edge =  $a$ , and radius of inscribed sphere =  $r$ . Then,

$$r = \frac{3V}{A_t}, \text{ and:}$$

Number of Faces	Form of Faces	Total Area $A_t$	Volume $V$
4	Equilateral triangle	$1.7321 a^2$	$0.1179 a^3$
6	Square	$6.0000 a^2$	$1.0000 a^3$
8	Equilateral triangle	$3.4641 a^2$	$0.4714 a^3$
12	Regular pentagon	$20.6457 a^2$	$7.6631 a^3$
20	Equilateral triangle	$8.6603 a^2$	$2.1817 a^3$

(Factors shown only to four decimal places.)

Table 32d. Solids Having Curved Surfaces

**Notation.** Lines,  $a, b, c, \dots$ ; altitude (perpendicular height),  $h, h_1, \dots$ ; slant height,  $s$ ; radius,  $r$ ; perimeter of base,  $p_b$ ; perimeter of a right section,  $p_r$ ; angle in radians,  $\phi$ ; arc,  $s$ ; chord of segment,  $l$ ; rise,  $h$ ; area of base,  $A_b$  or  $A_B$ ; area of a right section,  $A_r$ ; total area of convex surface,  $A_t$ ; total area of all surfaces,  $A_t$ ; volume,  $V$ .

**31. Right Circular Cylinder (and Truncated Right Circular Cylinder)**

*For Right Circular Cylinder:*

$$A_t = 2\pi rh; A_t = 2\pi r(r + h);$$

$$V = \pi r^2 h.$$

*For Truncated Right Circular Cylinder:*

$$A_t = \pi r(h_1 + h_2); A_t = \pi r \left[ h_1 + h_2 + r + \sqrt{r^2 + \left(\frac{h_1 - h_2}{2}\right)^2} \right];$$

$$V = \frac{\pi r^2}{2} (h_1 + h_2).$$

**32. Ungula (Wedge) of Right Circular Cylinder**

$$A_t = \frac{2r\phi}{b} [a + (b - r)\phi];$$

$$V = \frac{h}{3b} [a(3r^2 - a^2) + 3r^2(b - r)\phi]$$

$$= \frac{hr^3}{b} \left[ \sin \phi - \frac{\sin^3 \phi}{3} - \phi \cos \phi \right].$$

*For Semicircular Base (letting  $a = b = r$ ):*

$$A_t = 2r\phi; V = \frac{2r^3\phi}{3}.$$

**33. General Cylinder**

$$A_t = p_b h = p_r s;$$

$$V = A_b h = A_r s.$$

**34. Right Circular Cone (and Frustum of Right Circular Cone)**

*For Right Circular Cone:*

$$A_t = \pi r s = \pi r_B \sqrt{r_B^2 + h^2}; A_t = \pi r_B (r_B + s);$$

$$V = \frac{\pi r_B^2 h}{3}.$$

*For Frustum of Right Circular Cone:*

$$s = \sqrt{h^2 + (r_B - r_b)^2}; A_t = \pi s (r_B + r_b);$$

$$V = \frac{\pi h}{3} (r_B^2 + r_b^2 + r_B r_b).$$

**35. General Cone (and Frustum of General Cone)**

*For General Cone:*

$$V = \frac{A_b h}{3}.$$

*For Frustum of General Cone:*

$$V = \frac{h}{3} (A_B + A_b + \sqrt{A_B A_b}).$$

**36. Sphere**

Let diameter =  $d$ .

$$A_t = 4\pi r^2 = \pi d^2;$$

$$V = \frac{4\pi r^3}{3} = \frac{\pi d^3}{6}.$$

**37. Spherical Sector (and Hemisphere)**

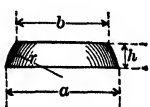

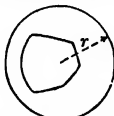

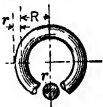

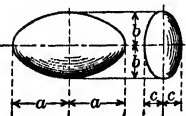

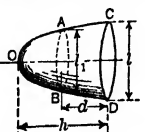

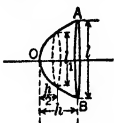

*For Spherical Sector:*

$$A_t = \frac{\pi r}{2} (4h + l); V = \frac{2\pi r^2 h}{3}.$$

*For Hemisphere (letting  $h = \frac{l}{2} = r$ ):*

$$A_t = 3\pi r^2; V = \frac{2\pi r^3}{3}.$$

(Table continued on p. 20-62)

Table 32d. Solids Having Curved Surfaces—Continued

## 44. Surface and Solid of Revolution

Let perpendicular distance from axis to center of gravity ( $G$ ) of curve (or surface) =  $r$ . Curve (or surface) must not cross axis. Then, Area of Surface generated by curve revolving about axis:

$$A_1 = 2\pi rs.$$

Volume of Solid generated by surface revolving about axis:

$$V = 2\pi rA.$$

## 45. Irregular Solid

One of the following methods can often be employed to determine the volume of an irregular solid with a reasonable approach to accuracy:

(a) Divide the solid into prisms, cylinders, etc., and sum their individual volumes.

(b) Divide one surface into triangles, after replacing curved lines by straight ones and curved surfaces by plane ones. Then multiply the area of each triangle by the mean depth of the section beneath it (which generally approximates the average of the depths at its corners). Sum the volumes thus obtained.

(c) If two surfaces are parallel, replace any curved lateral surfaces by plane surfaces best suited to the contour and then employ the prismatoidal formula.

## 6. ANALYTIC GEOMETRY

See Eshbach's *Handbook of Engineering Fundamentals*, pages 2-61 and 2-72 (Point and Line; Transformation of Coordinates; Conic Sections; Point, Line, and Plane; Quadric Surfaces).

## TRIGONOMETRY

## 7. CIRCULAR FUNCTIONS OF PLANE ANGLES

**Trigonometric Functions.** The angle  $\alpha$  in Fig. 1, is measured in degrees or radians, as defined in Table 14. The ratio of any two of the quantities  $x$ ,  $y$ , or  $r$  determines the extent of the opening between the lines  $OP$  and  $OX$ . Since these ratios are functions of the angle they may be used to measure or construct it. The definitions and terms used to designate the functions are as follows:

$$\text{Sine } \alpha = \frac{y}{r} = \sin \alpha$$

$$\text{Cosine } \alpha = \frac{x}{r} = \cos \alpha$$

$$\text{Tangent } \alpha = \frac{y}{x} = \tan \alpha$$

FIG. 1

$$\text{Cotangent } \alpha = \frac{x}{y} = \cot \alpha$$

$$\text{Secant } \alpha = \frac{r}{x} = \sec \alpha$$

$$\text{Cosecant } \alpha = \frac{r}{y} = \csc \alpha$$

$$\text{Versine } \alpha = \frac{r - x}{r} = \text{vers } \alpha = 1 - \cos \alpha$$

$$\text{Coversine } \alpha = \frac{r - y}{r} = \text{covers } \alpha = 1 - \sin \alpha$$

$$\text{Haversine } \alpha = \frac{r - x}{2r} = \text{hav } \alpha = \frac{1}{2} \text{vers } \alpha$$

**Positive and Negative Values.** An angle  $\alpha$  (Fig. 1), if measured in a *counter-clockwise* direction, is said to be *positive*; if measured *clockwise*, *negative*. Following the convention that  $x$  is positive if measured along  $OX$  to the right of the  $OY$  axis and negative if measured to the left, and similarly,  $y$  is positive if measured along  $OY$  above the  $OX$  axis and negative if measured below, the signs of the trigonometric functions are different for angles in the quadrants I, II, III, and IV. The signs of the six most common functions are tabulated in Table 33.

Table 33. Signs of Trigonometric Functions

Quadrant	sin	cos	tan	cot	sec	csc
I	+	+	+	+	+	+
II	+	-	-	-	-	+
III	-	-	+	+	+	-
IV	-	+	-	-	-	-

**Values of Trigonometric Functions** are periodic, the period of the sin, cos, sec, csc being  $2\pi$  radians, and that of the tan and cot,  $\pi$  radians. For example, in Fig. 2, ( $n$  an integer)

$$\sin(\alpha + 2\pi n) = \sin \alpha$$

$$\tan(\alpha + \pi n) = \tan \alpha$$

FIG. 2

Functions of angles in any quadrant (Fig. 1) in terms of angles in the first quadrant, and values of the functions for certain angles are given in Tables 34 and 35, respectively. Values of the functions for angles in increments of one-tenth of a degree may be obtained from the table of Trigonometric Functions beginning on p. 20-67.

Table 34. Functions of Angles in Any Quadrant in Terms of Angles in the First Quadrant

	$-\alpha$	$90^\circ \pm \alpha$	$180^\circ \pm \alpha$	$270^\circ \pm \alpha$	$360^\circ \pm \alpha$
sin	$-\sin \alpha$	$+\cos \alpha$	$\mp \sin \alpha$	$-\cos \alpha$	$\pm \sin \alpha$
cos	$+\cos \alpha$	$\mp \sin \alpha$	$-\cos \alpha$	$\pm \sin \alpha$	$+\cos \alpha$
tan	$-\tan \alpha$	$\mp \cot \alpha$	$\pm \tan \alpha$	$\mp \cot \alpha$	$\pm \tan \alpha$
cot	$-\cot \alpha$	$\mp \tan \alpha$	$\pm \cot \alpha$	$\mp \tan \alpha$	$\pm \cot \alpha$
sec	$+\sec \alpha$	$\mp \csc \alpha$	$\pm \sec \alpha$	$\mp \csc \alpha$	$+\sec \alpha$
csc	$-\csc \alpha$	$+\sec \alpha$	$\mp \csc \alpha$	$-\sec \alpha$	$\pm \csc \alpha$

$$a^2 = b^2 + c^2 - 2bc \cos \alpha \quad (\text{Law of Cosines})$$

$$\frac{a-b}{a+b} = \frac{\tan \frac{1}{2}(\alpha - \beta)}{\tan \frac{1}{2}(\alpha + \beta)} \quad (\text{Law of Tangents})$$

$$\alpha + \beta + \gamma = 180^\circ$$

$$a = b \cos \gamma + c \cos \beta; b = c \cos \alpha + a \cos \gamma; c = a \cos \beta + b \cos \alpha$$

$$A = \sqrt{s(s-a)(s-b)(s-c)}$$

$$\sin \alpha = \frac{2}{bc} A; \sin \beta = \frac{2}{ca} A; \sin \gamma = \frac{2}{ab} A$$

$$\sin \frac{\alpha}{2} = \sqrt{\frac{(s-b)(s-c)}{bc}}; \sin \frac{\beta}{2} = \sqrt{\frac{(s-c)(s-a)}{ca}}; \sin \frac{\gamma}{2} = \sqrt{\frac{(s-a)(s-b)}{ab}}$$

$$\cos \frac{\alpha}{2} = \sqrt{\frac{s(s-a)}{bc}}; \cos \frac{\beta}{2} = \sqrt{\frac{s(s-b)}{ca}}; \cos \frac{\gamma}{2} = \sqrt{\frac{s(s-c)}{ab}}$$

$$\tan \frac{\alpha}{2} = \sqrt{\frac{(s-b)(s-c)}{s(s-a)}}; \tan \frac{\beta}{2} = \sqrt{\frac{(s-c)(s-a)}{s(s-b)}}; \tan \frac{\gamma}{2} = \sqrt{\frac{(s-a)(s-b)}{s(s-c)}}$$

**Solution of Plane Oblique Triangles.**

**Given  $a, b, c$ .** (If logarithms are to be used, use 1.)

$$1. r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}; A = \sqrt{s(s-a)(s-b)(s-c)} = rs;$$

$$\tan \frac{\alpha}{2} = \frac{r}{s-a}; \tan \frac{\beta}{2} = \frac{r}{s-b}; \tan \frac{\gamma}{2} = \frac{r}{s-c}.$$

$$2. \cos \alpha = \frac{b^2 + c^2 - a^2}{2bc}; \cos \beta = \frac{a^2 + c^2 - b^2}{2ac};$$

$$\cos \gamma = \frac{a^2 + b^2 - c^2}{2ab}, \text{ or } \gamma = 180^\circ - (\alpha + \beta).$$

**Given  $a, b, \alpha$ .**

$$\sin \beta = \frac{b \sin \alpha}{a} \text{ (if } a > b, \beta < \frac{\pi}{2} \text{ and has only one value; if } b > a, \beta \text{ has two values, } \beta_1 \text{ and } \beta_2 = 180^\circ - \beta_1); \gamma = 180^\circ - (\alpha + \beta); c = \frac{a \sin \gamma}{\sin \alpha}; A = \frac{1}{2} ab \sin \gamma.$$

**Given  $a, \alpha, \beta$ .**

$$b = \frac{a \sin \beta}{\sin \alpha}; \gamma = 180^\circ - (\alpha + \beta); c = \frac{a \sin \gamma}{\sin \alpha}; A = \frac{1}{2} ab \sin \gamma.$$

**Given  $a, b, \gamma$ .** (If logarithms are to be used, use 1.)

$$1. \tan \frac{1}{2}(\alpha - \beta) = \frac{a-b}{a+b} \cot \frac{1}{2}\gamma; \frac{1}{2}(\alpha + \beta) = 90^\circ - \frac{1}{2}\gamma; c = \frac{a \sin \gamma}{\sin \alpha}$$

$$A = \frac{1}{2} ab \sin \gamma.$$

$$2. c = \sqrt{a^2 + b^2 - 2ab \cos \gamma}; \sin \alpha = \frac{a \sin \gamma}{c}; \beta = 180^\circ - (\alpha + \gamma).$$

$$3. \tan \alpha = \frac{a \sin \gamma}{b - a \cos \gamma}; \beta = 180^\circ - (\alpha + \gamma); c = \frac{a \sin \gamma}{\sin \alpha}.$$

**Solution of Plane Right Triangles.** Let  $\gamma = 90^\circ$  and  $c$  be the hypotenuse. Given any two sides or one side and an acute angle  $\alpha$ .

$$a = \sqrt{c^2 - b^2} = \sqrt{(c+b)(c-b)} = b \tan \alpha = c \sin \alpha.$$

$$b = \sqrt{c^2 - a^2} = \sqrt{(c+a)(c-a)} = \frac{a}{\tan \alpha} = c \cos \alpha.$$

$$c = \sqrt{a^2 + b^2} = \frac{a}{\sin \alpha} = \frac{b}{\cos \alpha}.$$

$$\alpha = \sin^{-1} \frac{a}{c} = \cos^{-1} \frac{b}{c} = \tan^{-1} \frac{a}{b}; \beta = 90^\circ - \alpha.$$

$$A = \frac{ab}{2} = \frac{a^2}{2 \tan \alpha} = \frac{b^2 \tan \alpha}{2} = \frac{c^2 \sin 2\alpha}{4}.$$

## 9. TRIGONOMETRIC FUNCTIONS

The following tables give the values of  $\sin x$ ,  $\cos x$ , and  $\tan x$  for values of  $x$  from 0 to  $90^\circ$  in intervals of 0.1 degree. By making use of the periodic character of these functions, the values can be determined from these tables for all values of  $x$  to an accuracy of 0.1 degree. (See Trigonometric Formulas.)

If the angle is given in radians multiply the number of radians by  $\frac{180}{\pi}$  (57.295) to obtain the number of degrees.

Table 37. Trigonometric Functions

0.0°-15.9°

## CALCULUS

## 10. DIFFERENTIAL CALCULUS

**Definition of a Function.** A variable  $y$  is said to be a function of a variable  $x$  if the value of  $y$  is determined when the value of  $x$  is given. In this definition,  $x$  is called the independent variable and  $y$  the dependent variable. The symbols  $F(x)$ ,  $f(x)$ ,  $\phi(x)$ , etc., are used to represent various functions of  $x$ , while the symbol  $f(a)$  represents the value of  $f(x)$  when  $x = a$ .

**Limit, Derivative, Differential, Continuity.** The constant  $a$  is said to be the *limit* of a variable  $x$ , if, as the variable changes its value, the numerical difference between the variable and constant becomes and remains less than any small positive constant which may be assigned. The symbol  $x \rightarrow a$  or  $\lim x = a$  is used for this definition. An example of a variable becoming equal to its limit is a swinging pendulum finally coming to rest. An illustration of a variable never reaching its limit is a polygon of  $n$  sides inscribed in a circle. No matter how large  $n$  is taken, the circumference of area of the polygon never equals that of the circle.

$x$  becomes *infinitely large*,  $x \rightarrow \infty$ , means that the value of  $x$  becomes *larger* than any assigned *positive* number.  $x \rightarrow -\infty$  means that the value of  $x$  becomes *smaller* than any assigned *negative* number.

Usually a change in  $x$  causes a change in  $y$ . A change in  $x$  is called an *increment* of  $x$  and is denoted by  $\Delta x$ . Similarly a change in  $y$  is denoted by  $\Delta y$ . If

$$\lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

has a *definite* value, it is called the *derivative* of  $y$  with respect to  $x$  and is denoted by  $\frac{dy}{dx}$  or  $f'(x)$ .

The geometric interpretation of  $f'(x)$  is

$$f'(x) = \frac{dy}{dx} = \tan \theta \quad (1)$$

or  $f'(x)$  is equal to the slope of the tangent to the curve  $y = f(x)$  at the point of contact  $P(x, y)$  (Fig. 1).

$$\lim_{\Delta x \rightarrow 0} \frac{RQ}{PR} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x} = \frac{dy}{dx} = f'(x) = \tan \theta \quad (2)$$

The differentials of  $x$  and  $y$ , respectively, are

$$dx = \Delta x$$

$$dy = f'(x)dx$$

**Continuity of a Function in an Interval.** A function is called *continuous* at  $x = b$  if it has a definite value at  $b$  and approaches that value as a limit whenever  $x$  approaches  $b$  as a limit. The notion of continuity at a point suggests that the graph of the function is a smooth curve in the neighborhood of the point. The analytic conditions that  $f(x)$  be continuous at  $b$  are that  $f(b)$  have a definite value and that

$$|f(x) - f(b)| < \epsilon \text{ for } |x - b| < \delta(\epsilon) \quad (3)$$

FIG. 1

where  $\epsilon$  is any positive number which can be chosen as small as desired, while  $\delta(\epsilon)$  depends on  $\epsilon$ . The bars outside of  $|f(x) - f(b)|$  show that the *absolute value* or value without the algebraic sign is to be taken; thus  $|2 - 5| = |5 - 2| = 3$ . A function which is continuous at each point of an interval is said to be continuous

in that interval. An example of a continuous function is  $f(x) = x^2$ . The function  $\phi(x) = \frac{1}{x-a}$  is continuous for all values of  $x$  other than  $x = a$ , at which point it becomes

infinite. Every differentiable function is continuous, although the reverse is not always true.

If, in the above definition of continuity, the number  $\delta$  can be chosen the same for all points in the interval, the function is said to be *uniformly continuous* in that interval.

**Derivatives of Higher Order.** The derivative of the first derivative of  $y$  with respect to  $x$  is called the *second derivative of  $y$  with respect to  $x$*  and is denoted by

$$\frac{d}{dx} \left( \frac{dy}{dx} \right) = \frac{d^2y}{dx^2} \quad \text{or} \quad f''(x) \quad (4)$$

$$\frac{d^3y}{dx^3} \quad \text{or} \quad f'''(x) \quad (5)$$

is the third derivative of  $y$  with respect to  $x$ . If  $y = f(x)$ , the second differential of  $f(x)$  is

$$d^2f = f''(x)dx^2 \quad (6)$$

### Indeterminate Forms

If a function  $f(x)$  for  $x = a$  (where  $a$  can also be  $\infty$ ) has no determined value but appears in one of the meaningless forms

$$\frac{0}{0}, \frac{\infty}{\infty}, 0 \cdot \infty, \infty - \infty, 0^0, \infty^0, 0^\infty, 1^\infty$$

then it may happen that the  $\lim_{x \rightarrow a} f(x)$  has a definite value. For the determination of this limiting value, if it exists, the following rules can be used:

$$\frac{0}{0}. \quad \text{If } f(x) = \frac{\phi(x)}{\psi(x)}, \phi(a) = 0, \text{ and } \psi(a) = 0, \text{ then}$$

$$\lim_{x \rightarrow a} f(x) = \lim_{x \rightarrow a} \frac{\phi'(x)}{\psi'(x)} \quad (\text{L'Hospital's rule}) \quad (7)$$

If, however,  $\phi'(a) = 0$  and  $\psi'(a) = 0$ , the rule is applied again, with the result

$$\lim_{x \rightarrow a} \frac{\phi(x)}{\psi(x)} = \lim_{\xi \rightarrow a} \frac{\phi'(\xi)}{\psi'(\xi)} = \frac{\phi''(a)}{\psi''(a)} \quad (8)$$

unless  $\phi''(a) = 0$  and  $\psi''(a) = 0$ . In this case, the rule is applied again.

**Example.** Find the value of  $\frac{\sin x}{x}$  for  $x = 0$ .

$$\lim_{x \rightarrow 0} \frac{\sin x}{x} = \lim_{x \rightarrow 0} \frac{\cos x}{1} = 1.$$

$$\frac{\infty}{\infty}. \quad \text{If } f(x) = \frac{\phi(x)}{\psi(x)}, \phi(a) = \infty, \text{ and } \psi(a) = \infty, \text{ then}$$

$$\lim_{x \rightarrow a} \frac{\phi(x)}{\psi(x)} = \lim_{x \rightarrow a} \frac{\phi'(x)}{\psi'(x)} \quad (9)$$

as before.

$0 \cdot \infty$ . If  $f(x) = \phi(x) \cdot \psi(x)$ ,  $\phi(a) = 0$ , and  $\psi(a) = \infty$ , then place  $\frac{1}{\psi(x)} = \omega(x)$  and obtain the previous case  $\frac{0}{0}$ .

$\infty - \infty$ . If  $f(x) = \phi(x) - \psi(x)$ ,  $\phi(a) = \infty$ , and  $\psi(a) = \infty$ , then place  $\phi(x) = \frac{1}{u(x)}$ .  $\psi(x) = \frac{1}{v(x)}$  and obtain

$$f(x) = \frac{v(x) - u(x)}{u(x)v(x)} \quad (10)$$

which takes the form  $\frac{0}{0}$ .

$0^0$ ,  $\infty^0$ ,  $0^\infty$ ,  $1^\infty$ . An expression of the type  $[\psi(x)]^{\phi(x)}$  may, for  $x = a$ , give rise to the forms  $0^0$ ,  $\infty^0$ ,  $0^\infty$ ,  $1^\infty$ .

Such an expression may be reduced to a type  $\frac{0}{0}$  or  $\frac{\infty}{\infty}$  by the use of logarithms. Thus,

$$u = [\psi(x)]^{\phi(x)} \\ \log_e u = \phi(x) \cdot \log_e \psi(x) \quad (11)$$

If  $\lim_{x \rightarrow a} \phi(x) \cdot \log_e \psi(x)$  can be found by the previous methods, the limit approached by  $u$  can be found.

**Example.**  $u = (1-x)^{1/x}$  for  $x = 0$

$$\log_e u = \frac{\log_e (1-x)}{x} \\ \lim_{x \rightarrow 0} \frac{\log_e (1-x)}{x} = -1$$

Therefore  $\lim_{x \rightarrow 0} \log_e u = -1$  and  $\lim_{x \rightarrow 0} u = e^{-1}$

**Table 38. Differentiation Formulas**

Let  $u, v, w, \dots$  be functions of  $x$ ;  $a$  and  $n$  be constants; and  $e$  be the base of the natural or Napierian logarithms. Then  $e = 2.7183$ .

$$\frac{d}{dx} a = 0$$

$$\frac{d}{dx} (u + v + w + \dots) = \frac{du}{dx} + \frac{dv}{dx} + \frac{dw}{dx} + \dots$$

$$\frac{d}{dx} au = a \frac{du}{dx}$$

$$\frac{d}{dx} uv = u \frac{dv}{dx} + v \frac{du}{dx}$$

$$\frac{d}{dx} (uvw \dots) = \left( \frac{1}{u} \frac{du}{dx} + \frac{1}{v} \frac{dv}{dx} + \frac{1}{w} \frac{dw}{dx} + \dots \right) (uvw \dots)$$

$$\frac{d}{dx} \left( \frac{u}{v} \right) = \frac{v \frac{du}{dx} - u \frac{dv}{dx}}{v^2}$$

$$\frac{d}{dx} u^n = nu^{n-1} \frac{du}{dx}$$

$$\frac{d}{dx} \log_e u = \frac{1}{u} \frac{du}{dx}$$

$$\frac{d}{dx} \log_{10} u = \frac{1}{u} \frac{du}{dx} \log_{10} e = (0.4343) \frac{1}{u} \frac{du}{dx}$$

$$\frac{d}{dx} e^u = e^u \frac{du}{dx}$$

$$\frac{d}{dx} u^v = vu^{v-1} \frac{du}{dx} + u^v \frac{dv}{dx} \log_e u$$

$$\frac{d}{dx} f(u) = \frac{df(u)}{du} \cdot \frac{du}{dx}$$

$$\frac{d^2 f(u)}{dx^2} = \frac{df(u)}{du} \cdot \frac{d^2 u}{dx^2} + \frac{d^2 f(u)}{du^2} \left( \frac{du}{dx} \right)^2$$

$$\frac{d}{dx} \sin u = \cos u \frac{du}{dx}$$

$$\frac{d}{dx} \cos u = -\sin u \frac{du}{dx}$$

$$\frac{d}{dx} \tan u = \sec^2 u \frac{du}{dx}$$

$$\frac{d}{dx} \cot u = -\csc^2 u \frac{du}{dx}$$

$$\frac{d}{dx} \sec u = \sec u \tan u \frac{du}{dx}$$

$$\frac{d}{dx} \csc u = -\csc u \cot u \frac{du}{dx}$$

$$\frac{d}{dx} \sin^{-1} u = \frac{1}{\sqrt{1-u^2}} \frac{du}{dx} \left( -\frac{\pi}{2} \leq \sin^{-1} u \leq \frac{\pi}{2} \right)$$

$$\frac{d}{dx} \cos^{-1} u = -\frac{1}{\sqrt{1-u^2}} \frac{du}{dx} \left( 0 \leq \cos^{-1} u \leq \pi \right)$$

$$\frac{d}{dx} \tan^{-1} u = \frac{1}{1+u^2} \frac{du}{dx}$$

$$\frac{d}{dx} \cot^{-1} u = -\frac{1}{1+u^2} \frac{du}{dx}$$

$$\frac{d}{dx} \sec^{-1} u = \frac{1}{u \sqrt{u^2-1}} \frac{du}{dx} \bullet$$

$$\frac{d}{dx} \csc^{-1} u = -\frac{1}{u \sqrt{u^2-1}} \frac{du}{dx} \bullet$$

$$\frac{d}{dx} \sinh u = \cosh u \frac{du}{dx}$$

$$\frac{d}{dx} \cosh u = \sinh u \frac{du}{dx}$$

$$\frac{d}{dx} \tanh u = \text{sech}^2 u \frac{du}{dx}$$

$$\frac{d}{dx} \coth u = -\text{csch}^2 u \frac{du}{dx}$$

$$\frac{d}{dx} \text{sech} u = -\text{sech} u \tanh u \frac{du}{dx}$$

$$\frac{d}{dx} \text{csch} u = -\text{csch} u \coth u \frac{du}{dx}$$

$$\frac{d}{dx} \sinh^{-1} u = \frac{1}{\sqrt{u^2+1}} \frac{du}{dx}$$

$$\frac{d}{dx} \cosh^{-1} u = \frac{1}{\sqrt{u^2-1}} \frac{du}{dx}$$

$$\frac{d}{dx} \tanh^{-1} u = \frac{1}{1-u^2} \frac{du}{dx}$$

$$\frac{d}{dx} \coth^{-1} u = \frac{1}{1-u^2} \frac{du}{dx}$$

$$\frac{d}{dx} \text{sech}^{-1} u = -\frac{1}{u \sqrt{1-u^2}} \frac{du}{dx}$$

$$\frac{d}{dx} \text{csch}^{-1} u = -\frac{1}{u \sqrt{u^2+1}} \frac{du}{dx}$$

\* For angles in the first and third quadrants. Use the opposite sign in the second and fourth quadrants.

**SERIES EXPANSION OF FUNCTIONS. Taylor's Formula.** If  $f(x)$  and all its derivatives are continuous in the neighborhood of the point  $x = a$ , then  $f(x)$  can be developed into a power series arranged according to ascending powers of  $x - a$ . The series is:

$$f(x) = f(a) + \frac{f'(a)}{1!} (x - a) + \frac{f''(a)}{2!} (x - a)^2 + \dots + \frac{f^{(n-1)}(a)}{(n-1)!} (x - a)^{n-1} + R_n \quad (12)$$

where  $n! = n(n-1)(n-2) \dots 2 \cdot 1$ , and is called factorial  $n$ , and

$$R_n = \frac{f^{(n)}(\xi)}{n!} (x - a)^n \quad (13)$$

is the *remainder* after  $n$  terms of the series and

$$\xi = a + \theta(x - a), \quad 0 < \theta < 1 \quad (14)$$

Another form:

$$f(x + h) = f(x) + \frac{h}{1!} f'(x) + \frac{h^2}{2!} f''(x) + \dots + \frac{h^{n-1}}{(n-1)!} f^{(n-1)}(x) + R_n \quad (15)$$

$$\text{where } R_n = \frac{h^n}{n!} f^{(n)}(\xi), \quad \xi = x + \theta h, \quad 0 < \theta < 1 \quad (16)$$

**Maclaurin's Form of Taylor's Formula** (for  $a = 0$ ).

$$f(x) = f(0) + \frac{f'(0)}{1!} x + \frac{f''(0)}{2!} x^2 + \dots + \frac{f^{(n-1)}(0)}{(n-1)!} x^{n-1} + R_n \quad (17)$$

$$\text{where } R_n = \frac{f^{(n)}(\xi)}{n!} x^n, \quad \xi = \theta x, \quad 0 < \theta < 1 \quad (18)$$

Care must be exercised in using these formulas that the *series converges*, that is,  $\lim_{n \rightarrow \infty} R_n = 0$ . If Taylor's series converges rapidly, the sum of the first few terms gives a good approximation to  $f(x)$  for values of  $x$  near  $x = a$ . If Maclaurin's series converges rapidly, the sum of the first few terms gives a good approximation to  $f(x)$  for values of  $x$  near  $x = 0$ . That not all functions can be expanded into Maclaurin's series is shown by the examples;  $f(x) = \frac{1}{x}$ ;  $\frac{1}{x^2}$ ;  $\sqrt{x}$ ;  $\frac{1}{\sqrt{x}}$ ;  $\log_e x$ ;  $\cot x$ ; etc.

**Example.** Expand  $e^{nx}$  into a series of ascending powers of  $x$ .

$$\begin{aligned} f(x) &= e^{nx}, & f(0) &= 1 \\ f'(x) &= n e^{nx}, & f'(0) &= n \\ f''(x) &= n^2 e^{nx}, & f''(0) &= n^2 \\ f'''(x) &= n^3 e^{nx}, & f'''(0) &= n^3 \\ f^{IV}(x) &= n^4 e^{nx}, & f^{IV}(0) &= n^4 \end{aligned}$$

$$e^{nx} = 1 + \frac{n}{1!} x + \frac{n^2}{2!} x^2 + \frac{n^3}{3!} x^3 + \dots$$

If  $x$  and  $n$  are less than unity, this series converges rapidly.

**Table 39. Functions Expanded into Series**  
( $\log = \log_e$ )

$(a + x)^n = a^n + na^{n-1}x + \frac{n(n-1)}{2!} a^{n-2}x^2 + \frac{n(n-1)(n-2)}{3!} a^{n-3}x^3 + \dots$	$(x^2 < a^2)$
$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \dots$	$(-\infty < x < \infty)$
$a^x = 1 + x \log a + \frac{(x \log a)^2}{2!} + \frac{(x \log a)^3}{3!} + \dots$	$(-\infty < x < \infty)$
$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \frac{x^8}{4!} - \dots$	$(-\infty < x < \infty)$
$e^{\sin x} = 1 + x + \frac{x^2}{2!} - \frac{3x^4}{4!} - \frac{8x^6}{5!} - \frac{3x^8}{6!} + \frac{56x^7}{7!} + \dots$	$(-\infty < x < \infty)$
$e^{\cos x} = e \left( 1 - \frac{x^2}{2!} + \frac{4x^4}{4!} - \frac{31x^6}{6!} + \dots \right)$	$(-\infty < x < \infty)$
$e^{\tan x} = 1 + x + \frac{x^2}{2!} + \frac{3x^3}{3!} + \frac{9x^4}{4!} + \frac{37x^5}{5!} + \dots$	$\left(-\frac{\pi}{2} < x < \frac{\pi}{2}\right)$
$\log x = \frac{x-1}{x} + \frac{1}{2} \left(\frac{x-1}{x}\right)^2 + \frac{1}{3} \left(\frac{x-1}{x}\right)^3 + \dots$	$\left(x > \frac{1}{2}\right)$
$\log x = 2 \left[ \frac{x-1}{x+1} + \frac{1}{3} \left(\frac{x-1}{x+1}\right)^3 + \frac{1}{5} \left(\frac{x-1}{x+1}\right)^5 + \dots \right]$	$(x > 0)$
$\log(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots$	$(-1 < x < 1)$
$\log \left(\frac{1+x}{1-x}\right) = 2 \left[ x + \frac{x^3}{3} + \frac{x^5}{5} + \frac{x^7}{7} + \dots \right]$	$(-1 < x < 1)$

Table 39. Functions Expanded into Series—Continued

$\log \left( \frac{x+1}{x-1} \right) = 2 \left[ \frac{1}{x} + \frac{1}{3} \left( \frac{1}{x} \right)^3 + \frac{1}{5} \left( \frac{1}{x} \right)^5 + \dots \right]$	$(-1 < x < 1)$
$\log \sin x = \log x - \frac{x^2}{6} - \frac{x^4}{180} - \frac{x^6}{2835} - \dots$	$(-\pi < x < \pi)$
$\log \cos x = -\frac{x^2}{2} - \frac{x^4}{12} - \frac{x^6}{45} - \frac{17x^8}{2520} - \dots$	$\left( -\frac{\pi}{2} < x < \frac{\pi}{2} \right)$
$\log \tan x = \log x + \frac{x^2}{3} + \frac{7x^4}{90} + \frac{62x^6}{2835} + \dots$	$\left( -\frac{\pi}{2} < x < \frac{\pi}{2} \right)$
$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$	$(-\infty < x < \infty)$
$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots$	$(-\infty < x < \infty)$
$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} + \frac{17x^7}{315} + \frac{62x^9}{2835} + \dots$	$\left( -\frac{\pi}{2} < x < \frac{\pi}{2} \right)$
$\cot x = \frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} - \frac{2x^5}{945} - \frac{x^7}{4725} - \dots$	$(-\pi < x < \pi)$
$\sec x = 1 + \frac{x^2}{2!} + \frac{5x^4}{4!} + \frac{61x^6}{6!} + \dots$	$\left( -\frac{\pi}{2} < x < \frac{\pi}{2} \right)$
$\csc x = \frac{1}{x} + \frac{x}{3!} + \frac{7x^3}{3 \cdot 5!} + \frac{31x^5}{3 \cdot 7!} + \dots$	$(-\pi < x < \pi)$
$\sin^{-1} x = x + \frac{x^3}{2 \cdot 3} + \frac{3x^5}{2 \cdot 4 \cdot 5} + \frac{3 \cdot 5x^7}{2 \cdot 4 \cdot 6 \cdot 7} + \dots$	$(-1 < x < 1)$
$\cos^{-1} x = \frac{\pi}{2} - \sin^{-1} x$

$\operatorname{csch}^{-1} x = \frac{1}{x} - \frac{1}{2 \cdot 3x^3} + \frac{3}{2 \cdot 4 \cdot 5x^5} - \frac{3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 7x^7} + \dots$	$(-1 > x > 1)$

## 11. INTEGRAL CALCULUS

**Integration** is the inverse operation of differentiation. It is indicated by the symbol  $\int$  followed by the differential function to be integrated. For example,

$$d(x^3) = 3x^2 dx \quad (1)$$

$$\text{and} \quad 3 \int x^2 dx = x^3 + c \quad (2)$$

$$\text{or in general} \quad \int f'(x) dx = f(x) + c \quad (3)$$

where  $f(x) + c$  is *indefinite* owing to the necessity of adding the arbitrary constant  $c$  whenever the operation of integration is performed.

$$\int_a^b f'(x) dx = f(b) - f(a) \quad (4)$$

is called the *definite integral*, where  $f'(x)$  is continuous in the interval  $a$  to  $b$  or has at most a finite number of finite discontinuities in the interval.

**Fundamental Forms.** Since integration is an anti-differentiation operation, facility in integrating depends upon the ability to recognize the forms of the derivatives of elementary functions and also the knowledge of how to transform a given function into an elementary form. Table 40 is a list of fundamental forms to which many integrals may be reduced by simple transformation.

**Integration by Parts** is a method frequently employed if it is advantageous to consider the integral of a function as the integral of the product of a function by the differential of another function; then

$$\int u dv = uv - \int v du \quad (5)$$

$$\text{since} \quad d(uv) = u dv + v du \quad (6)$$

where  $u$  and  $v$  are both functions of a variable  $x$ .

**Integration of Rational Fractions.** If the degree of the numerator is not less than that of the denominator in the equation

$$R(x) = \frac{\phi(x)}{f(x)}$$

where  $\phi(x)$  and  $f(x)$  are rational polynomials,  $R(x)$  can be put in the form of a polynomial and a remainder by performing the division indicated. The remainder may then be represented by partial fractions, and both the polynomial and remainder integrated directly by application of formulas 5, 6, 17, and 18 in Table 40.

**Integration of Irrational Functions** may frequently be accomplished by reducing them to rational integrals by changing the variable. The method is called integration by rationalization or integration by substitution.

For example, integrals containing the following forms may be rationalised by the substitutions indicated:

*Form*

$$\begin{aligned} & f[(ax + b)^{p/q}] dx \\ & f[(ax + b)^{p/q}(ax + b)^{r/s}] dx \\ & f[x, \sqrt{x^2 + ax + b}] dx \\ & f[x, \sqrt{-x^2 + ax + b}] dx \end{aligned}$$

$$\begin{aligned} & f[\sin x, \cos x] dx \\ & f[x, \sqrt{a^2 - x^2}] dx \\ & f[x, \sqrt{x^2 - a^2}] dx \\ & f[x, \sqrt{x^2 + a^2}] dx \end{aligned}$$

*Substitution*

$$\begin{aligned} & \text{let } ax + b = y^q \\ & \text{let } ax + b = y^n, \text{ where } n \text{ is the L.C.M. of } q, s \\ & \text{let } \sqrt{x^2 + ax + b} = y - x \\ & \text{let } \sqrt{-x^2 + ax + b} = \sqrt{(\alpha - x)(\beta + x)} \\ & \quad = (\alpha - x)y \text{ or } = (\beta + x)y \end{aligned}$$

$$\begin{aligned} & \text{let } \tan \frac{x}{2} = y \\ & \text{let } x = a \sin y \\ & \text{let } x = a \sec y \text{ or } x = a \cosh y \\ & \text{let } x = a \tan y \text{ or } x = a \sinh y \end{aligned}$$

Table 40. Table of Integrals

## Elementary Indefinite Integrals

1.  $\int a \, dx = ax + c$
2.  $\int (u + v + w + \dots) dx = \int u \, dx + \int v \, dx + \int w \, dx + \dots$
3.  $\int u \, dv = uv - \int v \, du$ , integration by parts
4.  $\int f(x) \, dx = \int f[\phi(y)] \phi'(y) dy$ ,  $x = \phi(y)$ , change of variable
5.  $\int x^n \, dx = \frac{x^{n+1}}{n+1} + c$ , ( $n \neq -1$ )
6.  $\int \frac{dx}{x} = \log_e x + c = \log_e c_1 x$ , [ $\log_e x = \log_e (-x) + (2k+1)\pi i$ ]
7.  $\int e^{ax} \, dx = \frac{1}{a} e^{ax} + c$
8.  $\int a^x \, dx = \frac{a^x}{\log_e a} + c$
9.  $\int a^x \log_c a \, dx = a^x + c$
10.  $\int \sin ax \, dx = -\frac{1}{a} \cos ax + c$
11.  $\int \cos ax \, dx = \frac{1}{a} \sin ax + c$
12.  $\int \tan ax \, dx = -\frac{1}{a} \log_e \cos ax + c = \frac{1}{a} \log_e \sec ax + c$
13.  $\int \cot ax \, dx = \frac{1}{a} \log_e \sin ax + c = -\frac{1}{a} \log_e \csc ax + c$
14.  $\int \sec ax \, dx = \frac{1}{a} \log_e (\sec ax + \tan ax) + c = \frac{1}{a} \log_e \tan \left( \frac{ax}{2} + \frac{\pi}{4} \right) + c$
15.  $\int \csc ax \, dx = \frac{1}{a} \log_e (\csc ax - \cot ax) + c = \frac{1}{a} \log_e \tan \frac{ax}{2} + c$
16.  $\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1} \frac{x}{a} + c = -\cos^{-1} \frac{x}{a} + c \quad (x^2 < a^2)$
17.  $\int \frac{dx}{a^2 + x^2} = \frac{1}{a} \tan^{-1} \frac{x}{a} + c = -\frac{1}{a} \cot^{-1} \frac{x}{a} + c$
18.  $\int \frac{dx}{x^2 - a^2} = \frac{1}{2a} \log \frac{x-a}{x+a} = -\frac{1}{a} \tanh^{-1} \frac{x}{a} = -\frac{1}{a} \coth^{-1} \frac{x}{a}$
19.  $\int \sinh ax \, dx = \frac{1}{a} \cosh ax + c$
20.  $\int \cosh ax \, dx = \frac{1}{a} \sinh ax + c$
21.  $\int \tanh ax \, dx = \frac{1}{a} \log_e (\cosh ax) + c$
22.  $\int \coth ax \, dx = \frac{1}{a} \log_e (\sinh ax) + c$
23.  $\int \operatorname{sech} ax \, dx = \frac{1}{a} \sin^{-1} (\tanh ax) + c$
24.  $\int \operatorname{csch} ax \, dx = \frac{1}{a} \log_e \left( \tanh \frac{ax}{2} \right) + c$
25.  $\int \sin^2 ax \, dx = \frac{1}{2} x - \frac{1}{2a} \sin ax \cos ax + c = \frac{1}{2} x - \frac{1}{4a} \sin 2ax + c$
26.  $\int \cos^2 ax \, dx = \frac{1}{2} x + \frac{1}{2a} \sin ax \cos ax + c = \frac{1}{2} x + \frac{1}{4a} \sin 2ax + c$
27.  $\int \tan^2 ax \, dx = \frac{1}{a} \tan ax - x + c$
28.  $\int \cot^2 ax \, dx = -\frac{1}{a} \cot ax - x + c$

Elementary Indefinite Integrals—Continued

29.  $\int \sec^2 ax \, dx = \frac{1}{a} \tan ax + c$
30.  $\int \csc^2 ax \, dx = -\frac{1}{a} \cot ax + c$
31.  $\int \sin^{-1} ax \, dx = x \sin^{-1} ax + \frac{1}{a} \sqrt{1 - a^2 x^2} + c$
32.  $\int \cos^{-1} ax \, dx = x \cos^{-1} ax - \frac{1}{a} \sqrt{1 - a^2 x^2} + c$
33.  $\int \tan^{-1} ax \, dx = x \tan^{-1} ax - \frac{1}{2a} \log_e (1 + a^2 x^2) + c$
34.  $\int \cot^{-1} ax \, dx = x \cot^{-1} ax + \frac{1}{2a} \log_e (1 + a^2 x^2) + c$
35.  $\int \sec^{-1} ax \, dx = x \sec^{-1} ax - \frac{1}{a} \log_e (ax + \sqrt{a^2 x^2 - 1}) + c$
36.  $\int \csc^{-1} ax \, dx = x \csc^{-1} ax + \frac{1}{a} \log_e (ax + \sqrt{a^2 x^2 - 1}) + c$

Integrals Involving  $(ax + b)$

37.  $\int (ax + b)^n \, dx = \frac{1}{a(n+1)} (ax + b)^{n+1} \quad (n \neq -1)$
38.  $\int \frac{dx}{ax + b} = \frac{1}{a} \log_e (ax + b)$
39.  $\int x(ax + b)^n \, dx = \frac{1}{a^2(n+2)} (ax + b)^{n+2} - \frac{b}{a^2(n+1)} (ax + b)^{n+1} \quad (n \neq -1, -2)$
40.  $\int \frac{x \, dx}{ax + b} = \frac{x}{a} - \frac{b}{a^2} \log_e (ax + b)$
41.  $\int \frac{x \, dx}{(ax + b)^2} = \frac{b}{a^2(ax + b)} + \frac{1}{a^2} \log_e (ax + b)$
42.  $\int \frac{x^2 \, dx}{ax + b} = \frac{1}{a^3} \left[ \frac{1}{2} (ax + b)^2 - 2b(ax + b) + b^2 \log_e (ax + b) \right]$
43.  $\int \frac{x^2 \, dx}{(ax + b)^2} = \frac{1}{a^3} \left[ (ax + b) - 2b \log_e (ax + b) - \frac{b^2}{ax + b} \right]$
44.  $\int \frac{x^2 \, dx}{(ax + b)^3} = \frac{1}{a^3} \left[ \log_e (ax + b) + \frac{2b}{ax + b} - \frac{b^2}{2(ax + b)^2} \right]$
- 45.
46.  $\int \frac{dx}{x^2(ax + b)} = -\frac{1}{bx} + \frac{a}{b^2} \log_e \frac{ax + b}{x}$
47.  $\int \frac{dx}{x(ax + b)^2} = \frac{1}{b(ax + b)} - \frac{1}{b^2} \log_e \frac{ax + b}{x}$
48.  $\int \frac{dx}{x^2(ax + b)^2} = -\frac{b + 2ax}{b^2 x(ax + b)} + \frac{2a}{b^3} \log_e \frac{ax + b}{x}$

## Greek Letters

A $\alpha$ Alpha	H $\eta$ Eta	N $\nu$ Nu	T $\tau$ Tau
B $\beta$ Beta	$\Theta$ $\theta$ Theta	$\Xi$ $\xi$ Xi	T $\upsilon$ Upsilon
$\Gamma$ $\gamma$ Gamma	I $\iota$ Iota	O $\omicron$ Omicron	$\Phi$ $\phi$ Phi
$\Delta$ $\delta$ Delta	K $\kappa$ Kappa	$\Pi$ $\pi$ Pi	X $\chi$ Chi
E $\epsilon$ Epsilon	$\Lambda$ $\lambda$ Lambda	P $\rho$ Rho	$\Psi$ $\psi$ Psi
Z $\zeta$ Zeta	M $\mu$ Mu	$\Sigma$ $\sigma$ Sigma	$\Omega$ $\omega$ Omega

## Mathematical Signs and Abbreviations

+ plus (addition).

+ positive.

- minus (subtraction).

- negative.

 $\pm$  plus or minus. $\mp$  minus or plus.

= equals.

 $\geq$  equals or greater than. $\leq$  equals or is less than. $\approx$  approximately equals. $\times$  multiplied by. $ab$  or  $a.b = a \times b$ .

+ divided by.

/ divided by.

$$\frac{a}{b} = a/b = a \div b. \quad 15/16 = \frac{15}{16}$$

$$0.2 = \frac{2}{10}; \quad 0.002 = \frac{2}{1000}$$

 $\sqrt{\quad}$  square root. $\sqrt[3]{\quad}$  cube root. $\sqrt[n]{\quad}$   $n$ th root.

: is to, :: so is, : to (proportion).

2 : 4 :: 3 : 6, 2 is to 4 as 3 is to 6.

: ratio; divided by.

2 : 4, ratio of 2 to 4 =  $2/4$ .

&gt; greater than.

&lt; less than.

 $^{\circ}$  degrees, arc or thermometer.

' minutes or feet.

" seconds or inches.

' ' ' ' accents to distinguish letters, as  $a'$ ,  $a''$ ,  $a'''$ . $a_1$ ,  $a_2$ ,  $a_3$ ,  $a_b$ ,  $a_c$ , read  $a$  sub 1,  $a$  sub  $b$ , etc.

( ) [ ] { } — parentheses, brackets, braces,  
vinculum; denoting that the numbers enclosed are to be taken together; as,  
( $a + b$ ) $c = 4 + 3 \times 5 = 35$ .

 $a^2$ ,  $a^3$ ,  $a$  squared,  $a$  cubed. $a^n$ ,  $a$  raised to the  $n$ th power.

$$a^{3/2} = \sqrt[3]{a^2}, \quad a^{2/3} = \sqrt{a^2}.$$

$$a^{-1} = \frac{1}{a}, \quad a^{-2} = \frac{1}{a^2}.$$

 $10^9 = 10$  to the 9th power = 1,000,000,000. $\sin a$  = the sine of  $a$ . $\sin^{-1} a$  = the arc whose sine is  $a$ .

$$\sin a^{-1} = \frac{1}{\sin a}.$$

 $\log$  = logarithm. $\log_e$  or  $\text{hyp log}$  = hyperbolic logarithm.

% per cent.

 $\angle$  angle. $\triangle$  triangle. $\sin$ , sine. $\cos$ , cosine. $\tan$ , tangent. $\sec$ , secant. $\text{versin}$ , versed sine. $\cot$ , cotangent. $\text{cosec}$ , cosecant. $\text{covers}$ , co-versed sine.

In Algebra, the first letters of the alphabet,  $a$ ,  $b$ ,  $c$ ,  $d$ , etc., are generally used to denote known quantities, and the last letters,  $w$ ,  $x$ ,  $y$ ,  $z$ , etc., unknown quantities.

*Abbreviations and Symbols commonly used.* $d$ , differential (in calculus). $\int$ , integral (in calculus). $\int_a^b$ , integral between limits  $a$  and  $b$ . $\Delta$ , delta, difference. $\Sigma$ , sigma, sign of summation. $\pi$ , pi, ratio of circumference of circle to diameter = 3.14159. $g$ , acceleration due to gravity = 32.16 ft. per second per second.

  - connecting rods, 13-42
  - cooling, 13-51
  - crankcase, 13-42
  - crankshafts, 13-42
  - cruising power, 13-52
  - cruising speed, 13-52

### Aircraft engines (*continued*)

- cylinder construction, 13-43
  - detonation, 13-47
  - dimensions, 13-52
  - displacement, 13-52
  - effect of altitude on output, 13-47
  - effect of compression ratio on performance, 13-47
  - effect of mixture ratio on performance, 13-46
  - effect of spark advance on performance, 13-46
  - effect of speed on performance, 13-46
  - Franklin, data, 13-52
  - fuel injection, 13-49
  - horizontally opposed, 13-42
  - ignition systems, 13-48
  - Jacobs, data, 13-53
  - Lycoming, data, 13-53
  - materials, 13-42
  - mechanical arrangement, 13-41
  - mixture ratio, 13-46
  - noise, 13-51, 13-55
  - performance, 13-44
  - performance factors, 13-45
  - piston rings, 13-43
  - pistons, 13-43
  - Pratt and Whitney, data, 13-53
  - preignition, 13-47
  - radial, 13-42
  - Ranger, data, 13-54
  - sleeve-valve, 13-44
  - spark plugs, 13-49
  - stress determinations, 13-55
  - structural components, 13-42
  - supercharging, 13-49
  - take-off power, 13-52
  - take-off speed, 13-52
  - thermodynamic characteristics, 13-41
  - valve mechanism, 13-43
  - valves, 13-43
  - Vee types, 13-42
  - vibration, 13-51
  - Warner, data, 13-54
  - Wright, data, 13-54
- Aircraft fuels**, 13-50
- Aircraft gas turbines (Table)**, 15-66
  - compressors, 15-55
- Aircraft materials**, 15-03
- Aircraft performance**, effect of altitude, 15-17
- Aircraft piston engines**, 13-40
  - history, 13-40
- Aircraft power plants**, 15-18
- Aircraft propellers**, coefficients, 15-20
  - reduction gears, 13-44
- Aircraft propulsion**, general principles, 15-38
- Aircraft structural analysis**, 15-23
- Aircraft structural materials**, weights (Table), 15-05
- Aircraft superchargers**, 10-04
- Airfoils**, 15-07
  - center-of-pressure of, 15-09
  - center-of-pressure travel, 15-09
  - characteristic curves, 15-08
  - circular-arc, 15-33
  - compressible-flow, 15-10
  - double-wedge, 15-33
  - flat plate, 15-33
  - laminar-flow, 15-10
  - moment coefficient, 15-09
  - section characteristics, 15-11
  - selection, 15-10
  - shapes of supersonic, 15-33
- Airplane power plants**, speed ranges, 15-19
- Airplane propellers**, 15-20
- Airplanes**, amphibian, 15-03 (*see also* Aircraft)

**Airplanes (continued)**

- Breguet's range formula, 15-18
- canard type, 15-03
- ceiling, 15-18
- center of gravity, 15-22
- classification, 15-02
- cruising speed, 15-18
- elements, 15-02
- empennage, 15-03
- interference drag, 15-16
- Jato for, 15-03
- landing gear, 15-03
- maximum speed, 15-17
- monocoque construction, 15-03
- parasite drag, 15-16
- performance analysis, 15-16
- power for horizontal flight, 15-17
- power loading, 15-18
- power-plant arrangement, 15-03
- range, 15-18
- rate of climb, 15-18
- structural design, 15-03
- tail surfaces, 15-03
- take-off, 15-03
- transport and personal (data), 15-04, 15-05
- tricycle gear, 15-03
- wing loading, 15-17

**Airships, 15-02**

- characteristics, 15-27
- performance, 15-27
- range, 15-27
- rigid, characteristics (Table), 15-27

**Airworthiness, 15-23****Alcohol, 2-59**

- critical-state properties, 3-60
- isopropyl, 14-63
- thermal conductivity, 3-15

**Alkalinity of feedwater, 7-52 •****All-American Aircraft, Inc., 15-05****Allison Division, General Motors Corp., turbojet units, 15-66****Allison engines, 13-52****Alloys, 10-35 (see also name of alloy)**

- composition of high temperature (Table), 10-35
- Inconel, 10-35
- melting points (Table), 3-07
- thermal conductivity, 3-13
- Timken, 10-35
- Vitallium (cast), 10-35

**Alternating-current locomotives, 14-46 (see also a-c entries)****Alternating-current power transmission, 16-04****Alternating-current ship propulsion, 15-78**

- Altitude, effect on aircraft engine output, 13-47
- effect on aircraft performance, 15-17
- effect on compressors, 1-47
- performance of aircraft engines at, 13-48
- rating of diesels at, 13-14

**Altitude correction, compressor, 1-48****Alumina, effect on feedwater, 7-51**

- removal from feedwater, 7-51
- solubility in feedwater, 7-52

**Aluminum, emissivity, 3-21**

- nuclear properties, 17-18
- thermal conductivity, 3-14

**Ambient effect on thermometers, 18-06****American Bureau of Shipping, 15-72****American Locomotive Co. diesel engine, 13-19****American propjets (Table), 15-68****American wire gage, B. & S., 16-08****Ammonia, 11-10 (see also NH<sub>3</sub>)**

- combustion, 2-04
- critical-state properties, 3-60
- data, 1-40

**Ammonia (continued)**

- gaseous, thermal conductivity, 3-16
- viscosity, 1-15
- liquid, thermal conductivity, 3-15
- properties (Table), 11-11
- superheated, chart, 11-12
- properties (Table), 11-14

**Ammonia-absorption refrigeration system, 11-31****Ammonia compressor performance (Table), 11-21****Ammonia condensers, dimensions (Table), 11-46****shell and tube-type (Table), 11-46****Ammonia solutions, specific volume (Table), 11-34****Ammonia-water solutions, 11-30****Amperes, formulas for (Table), 16-04****Analysis, airplane performance, 15-16**

- coal, 2-21
- coke (Tables), 2-38, 2-39
- dimensional, 5-04
- feedwater, 7-50

**Aneroid barometer, 19-06****Aneroid meter, 18-17****Angle of attack, 15-07****Angle valves, pressure loss, 6-39****Angles, functions of, 20-62****Angles of repose for coal, 2-32****Aniline cloud point, 13-33****Anion absorber in water treatment, 7-61****Annulus, geometry of the, 20-57****Anthracite coal, combustion, 2-04 (see also Coals)**

- composition (Table), 2-26

**Copper bars; sizes, weights, current capacity (Table), 16-06****Copper-constantan thermocouple (Tables), 18-07, 18-08****Copper pipe (Table), 6-32****Copper wire and cable, dimensions and resistance (Table), 16-07**

- sizes, weights (Table), 16-06

**Cord of wood, 2-40****Cork, conductivity, 11-37****Corn on the cob, heating value, 2-44****Correction, aspect ratio, 15-10**

- induced drag, 15-10

- Mach number, airfoil characteristics, 15-11

**Correction factors, convector heaters (Table), 12-15**

- power, automotive engine (Table), 14-90

- radiator (Table), 12-15

- turbine, 8-56

**Corrosion, air preheater, 7-38**

- boiler, 7-62

- causes of, 7-62

- economizer, 7-34

- at high temperature, 7-62

**Corrosion fatigue, 7-62**

- boiler, 7-62

**Cost, of boilers, 7-06**

- of diesel engines (Table), 13-25

- of diesel locomotives, 14-45

- of fly-ash collectors, 7-96

- of operating diesels per kilowatt hour, 13-26

- railroad switching, 14-43

- of steam-electric plants (Table), 16-96

**Cotton, thermal conductivity, 3-14****Cotton batting, heating value, 2-44****Cottonseed hulls, heating value, 2-44****Counterbalancing of locomotive wheels, 14-22****Counterflow cooling in cooling towers, 9-28****Counters, revolution, 19-04****Couplings, hydraulic, 5-83**

- turbine, 8-41

**Covered-tube furnace walls, 7-70****Crackage method of heat loss calculation, 12-10****Crank angle factor, for piston acceleration (Table), 14-71**

- for piston velocity (Table), 14-70

**Crankcase, of aircraft engines, 13-42****Crankpins, locomotive roller bearing, 14-19**

- stress in locomotive, 14-11

**Crankshafts, aircraft engine, 13-42**

- automotive, 14-65

- vibration, 14-65

**Creameries, refrigeration requirements, 11-43****Creep, in turbine materials, 8-92****Cresol red, 7-53****Critical flow equation, 1-12****Critical mass, in nuclear reactions, 17-12****Critical pressure, 3-61, 8-15****Critical pressure ratio, 1-13, 8-15**

- of gases (Table), 3-62

**Critical rate of flow, 1-13****Critical size, cube, in nuclear reactions, 17-12**

- cylinder, 17-12

- sphere, 17-12

**Critical speed, 8-36**

- centrifugal pump, 5-70

- engine, 13-18

- rotating elements, 1-108

- turbine rotor, 8-40

**Critical-state properties, various substances (Table), 3-60****Critical state for water, 4-03**

**Critical temperature**, 3-61  
**Critical viscosity**, temperature, 2-24  
**Cross-compound compressor**, 1-35  
**Cross-flow correction factor**, heat exchangers, 3-31  
**Cross sections**, nuclear, 17-07  
**Crossfeed stoker**, 2-35  
**Crossheads**, locomotive, 14-18  
**Cruising power**, aircraft engine, 13-52  
**Cruising speed**, aircraft engine, 13-52  
     airplane, 15-18  
**Crushing of coal**, 7-82  
**Cube roots of numbers**, 20-27  
**Cubes of numbers**, 20-27  
**Cubic foot**, equivalents (Table), 20-44  
**Cummins diesel engine**, 13-09, 13-18  
**Curies**, 17-19  
**Curran-Knowles coke ovens**, 2-38  
**Current**, balanced, 16-36  
     differential, 16-36  
     magnetizing, 16-41  
     power-producing, 16-41  
     short-circuit, 16-27  
**Current balance trip**, 16-32  
**Current capacity**, copper bars (Table), 16-06  
**Current meters**, flowing water, 5-20  
**Curtis stage**, turbines, 8-02  
**Curtiss-Wright Corp.**, 15-04  
**Curve resistance**, locomotive, 14-04  
**Cut-offs**, locomotive engine, 14-08  
**Cycle**, air-standard, 13-06  
     binary-vapor, 4-06  
     Carnot, 4-05  
     compound, gas turbine, 10-07  
     power plant, references, 4-29  
     refrigeration, 11-03  
     steam and binary, plant performance (Table), 8-93  
     steam-power, 4-02  
     steam regenerative, 4-05  
     steam regenerative-reheat, 4-06  
     steam reheat, 4-05  
     steam-turbine, 8-14  
**Cycle efficiency**, mercury, 8-95  
     modified gas turbine, 15-44  
**Cyclogyro**, 15-02  
**Cycloid**, geometry of, 20-58  
**Cylinder jackets**, cooling water requirements, 1-55  
**Cylinder lubrication**, rate of oil feed, 1-54  
     steam engine, 8-112  
**Cylinder oils**, characteristics, 1-54  
**Cylinders**, aircraft engine, construction, 13-43  
     general, geometry of, 20-60  
     number of, in typical internal combustion engines (Tables), 13-17, 13-18, 13-19  
     right circular, geometry of, 20-60  
**Damper control**, fans, 1-91  
     superheater, 7-28  
**Dams**, flow over, 5-18  
**Darcy formula**, 5-07  
**Davis formulas for tractive resistance**, 14-48  
**D-c to a-c power conversion**, 16-83 (*see also direct current entries*)  
**Dead time**, control systems, 18-29  
     controlled processes, 18-28  
**Deadweight gages**, 19-11  
**Deadweight of ships**, 15-69  
**Deaerating feedwater heater**, tray-type, 7-43  
**Deaerator**, atomizing, 7-44  
**Decimal equivalents of numbers**, 20-27  
**Degree-days** (Table), 12-22  
**Degrees**, API (def), 13-32

**Degrees** (*continued*)  
     decimals of, minutes and seconds (Table), 20-53  
     values of radians in (Table), 20-53  
**DeHaviland Aircraft Co. Ltd.**, turbojet, 15-67  
**Dehumidifying air washer**, 12-82  
**Delta-delta transformer connections**, 16-70  
**Delta-star transformer connections**, 16-70  
**Demand** (def), 16-99  
**Demand factor**, 16-12; 16-100 (def)  
**Demineralization treatment of water**, 7-61  
**Density**, air, 1-09 (*see also name of substance*)  
     of the atmosphere at altitude, 1-09  
     common fluids (Table), 5-03  
     flue gas in fan practice, 1-63  
     gas, 2-75  
     metric equivalents (Table), 20-48  
     of mixtures, 2-03  
**Deposits**, in air preheaters, 7-38  
     removal of turbine, 8-55  
     turbine, 8-26  
**Depreciable value**, 16-91  
**Depreciation**, 16-91  
     average rates (Table), 16-93  
     diminishing-value, 16-92  
     reducing-balance, 16-92  
     sinking-fund, 16-92  
     straight-line, 16-92  
**Depreciation accounting**, 16-92  
**Depreciation expense**, 16-91  
**Depth**, ships, 15-69  
**Design calculations**, turbojet, 15-53  
**Design considerations**, marine, 15-69  
**Design criteria**, gas turbine, 10-33  
**Design data**, air compressors, 1-44  
     air-removal systems, 9-19  
**Desuperheaters**, 7-28  
**Desuperheating in feedwater heaters**, 7-48  
**Detached shock**, 15-32  
**Detergent oils**, 14-69  
**Detonation**, aircraft engine, 13-47  
     automotive engine, 14-92  
**Dew-point temperature**, 12-74  
**Diagram factors**, steam engine (Table), 8-103  
**Diameter speed**, locomotive, 14-11  
**Diaphragm gages**, 18-17  
**Diaphragm motors**, 18-25  
**Diaphragms**, blow-out, 9-16  
     turbine, 8-51  
**Dichlorodifluoromethane** (Tables), 11-10, 11-13  
**Dichloroethylene**, 11-10, 11-18  
**Dichloromethane** (Tables), 1-40, 11-10  
**Dielene**, 11-10

- Radiation and convection**, combined, 3-30
- Radiation load**, 12-16
- Radiation pyrometers**, 18-13
  - accuracy, 18-14
- Radiation screens**, 3-41
- Radiation temperature factor**, curves, 3-23
- Radiator**, heating, 12-12 (*see also* Radiators)
- Radiator branch and riser sizes** (Table), 12-38
- Radiator valve capacities** (Table), 12-33
- Radiator valves**, rating (Table), 12-29
- Radiators**, anti-freeze for, 14-63
  - cast-iron, dimensions and ratings (Table), 12-14
  - correction factors (Table), 12-15
  - heat emission, 12-16
  - pressure caps for automotive, 14-63
  - rating of heating, 12-14
- Radioactive series**, 17-05
- Radioactivity**, 17-04
  - references, 17-20
- Radium**, nuclear properties, 17-19
- Radius**, hydraulic, 5-09
- Radius taps** (flow measurement), 1-16
- Rags**, heating value, 2-44
- Railcars**, diesel (Table), 14-41
  - diesel-powered, 14-40

- Ram jet**, 15-19, 15-42
- Range**, airplane, 15-18
  - airship, 15-27
  - thermocouple, 18-07
- Ranger engines**, 13-54
- Rank**, classification of coal by, 2-18
- Rankine cycle efficiency**, 4-04
- Rankine temperature** (def), 3-52
- Rankine temperature scale**, 18-02
- Rate action**, automatic controller, 18-24
  - control system, 18-30
- Rate schedule**, example, 16-10
  - power, 16-09
- Rateau stage**, turbine, 10-31
- Rating tests**, fan, 1-70
- Ratings**, fan, 1-81
  - radiator valve (Table), 12-29
  - refrigerating machine, 11-02
- Ratio**, aspect, 15-06, 15-11
  - structural material weight, aircraft (Table), 15-05
- Ratio control of two variables**, 18-38
- Raymond Bowl Mill**, pulverized-coal, 7-85
- Reactance diagram**, 16-30
- Reactance and resistance**, relation between, 16-05
- Reaction**, in steam turbine stages, 8-21
  - vortex design, 15-55
- Reaction blading**, 8-22
  - losses, 8-22
- Reaction curves**, typical process, 18-29
- Reaction hydraulic turbine**, 5-26, 5-27, 5-28
  - runners for, 5-31, 5-32
- Reaction stage**, gas turbine, 10-31
- Reactions**, chain, 17-07
  - gamma-ray, 17-06
  - neutron, 17-06
- Reactors**, control of nuclear, 17-15
  - design, 17-14
    - fast, 17-14
    - gaseous fuel, 17-13

**Separating calorimeter**, 7-22  
**Series**, radioactive, 17-05  
**Series expansions of functions** (Table), 20-75  
**Service life of property**, 16-91  
**Settings**, height of, stoker-equipped boilers (Table), 7-66  
**Shaft diameters**, first approximation, 8-38  
**Shale oil**, 2-60  
**Shape factor**, in fluid flow, 5-08  
**Sheathing**, thermal conductance of, 12-09  
**Sheet gage**, 16-08  
**Shell pressure curves**, turbine, 8-63  
**Shell-and-tube ammonia condensers** (Table), 11-46  
**Sheppard diesel engine**, 13-17, 13-18  
**Shield**, biological, 17-15  
**Ships**, alternating-current propulsion of, 15-78  
 auxiliaries, 15-81  
 boilers, 15-80  
 characteristics of U. S. (Table), 15-69  
 condensers, 15-80  
 direct-current propulsion, 15-78  
 distilling plants, 15-83  
 electric-drive, 15-78  
**Ships (continued)**  
 geared-turbine units for, 15-79  
 refrigeration of, 15-83  
 service machinery, 15-82  
 single-screw, 15-71  
 speed and power characteristics (Table), 15-70  
 twin-screw, 15-71  
**Shock**, 8-17, 15-28  
 applications, 15-33  
 bow, 15-32  
 data, 15-28  
 detached, 15-32  
 detachment of, 15-35  
**Shock patterns**, three-dimensional, 15-35  
 two-dimensional, 15-30  
**Shock theory**, 3-70  
**Shock waves**, 1-102, 15-29  
 conical, flow relations, 15-36  
 flow relations through, 15-36  
 forked, 15-35  
 normal, 15-29  
 flow relations (Table), 15-30  
 oblique, flow relations, 15-31  
**Shocks**, compression, 3-70  
**Short-circuit currents**, 16-27  
 asymmetrical, 16-27  
 calculation, 16-27  
 sources, 16-27  
**Short circuits**, three-phase, 16-30  
**Short tubes**, flow through, 5-09  
**Shrink fits for disks**, 8-35  
**Shrouds**, bucket, 8-24  
**Shutdown of gas turbines**, 10-46  
**Side rods**, locomotive, 14-11  
**Sieve**, U. S. standard, 7-85  
 W. S. Tyler, 7-85  
**Sigma**, cavitation constant, 5-67  
**Signal-system investment**, 16-90  
**Signaling**, controls for, 18-38  
**Sikorsky Aircraft Div.**, 15-25  
**Silica**, boiler scaling properties, 7-54  
 effect on feedwater, 7-51  
 removal from feedwater, 7-51  
 solubility in feedwater, 7-52  
**Silica gel**, 11-35  
**Silicon**, nuclear properties, 17-18  
**Sil-O-Cel**, thermal conductivity, 3-38  
**Silver**, emissivity, 3-21  
 nuclear properties, 17-18  
 thermal conductivity, 3-14  
**Similarity**, dynamic, 5-04  
**Simple impulse turbine**, 8-02  
**Simplex pump**, 5-72  
**Single phase circuits**, 16-04  
**Sinking-fund depreciation**, 16-92  
**Sinking pumps**, air required, 1-57  
**Size**, copper bar (Table), 16-06  
 screen, standard (Table), 7-85  
**Size and capacity**, commercial expansion tanks (Table), 12-39  
**Size and weights**, copper wire and cable (Table), 16-06  
**Sizing**, of pulverized coal, 7-82  
**Skating rinks (ice)**, refrigeration requirements, 11-43  
**Skidding coefficient of friction**, automobile, 14-81  
**Skin friction conduit losses**, 5-14  
**Sky radiation**, 3-26  
**Sky and solar radiation**, heat gain (Table), 12-78  
**Slab insulations**, thermal conductivity, 12-07  
**Slag-tap furnaces**, 7-81  
**Slagging furnaces**, 7-81  
**Slags**, viscosity of, 2-23  
**Slate**, thermal conductivity, 3-14

- Sleeve-valve aircraft engine**, 13-44
- Sliding angles**, coal, 2-32
- Slip-stem valves**, 18-27
- Slip-stream effect**, airplane, 15-16
- Slip-stream velocity**, 15-17
- Slots**, wing, 15-12; 15-13 (Table)
- Sluice gates**, discharge through, 5-11
- Smoke** (def), 7-91
- Smoke elimination**, 7-94
- Smoke ordinances**, reference, 7-97
- Snow**, thermal conductivity, 3-14
- Sodium**, thermal conductivity, 3-14
- Sodium aluminate**, feedwater treatment by, 7-58
- Sodium carbonate**, feedwater treatment by, 7-57
- Sodium chloride solutions**, boiling points (Table), 3-74  
specific heat (Table), 3-06
- Sodium compounds**, effect on feedwater, 7-51  
removal from feedwater, 7-51  
solubility in feedwater, 7-52
- Sodium-cycle cation exchangers**, 7-60
- Sodium-cycle exchangers for water treatment**, 7-58
- Sodium phosphate**, common forms of, 7-57  
feedwater treatment by, 7-57
- Softeners**, ion-exchange water, 7-58
- Soil**, average temperature, 12-03  
thermal conductivity, 3-14 (Table); 12-66
- Solar radiation** (Table), 3-25
- Solar and sky radiation**, heat gain from (Table), 12-78
- Solenoid valves**, 18-26
- Solid fuels**, 2-17  
references, 2-44
- Solid of revolution**, geometry of, 20-62
- Solids**, dissolved, in feedwater, 7-54  
expansion of (Table), 3-10  
in feedwater, test, 7-54  
nonmetallic, thermal conductivity, 3-13  
specific heat of (Table), 3-06
- Solubility of impurities in feedwater** (Table), 7-52
- Solutions of ammonia-water**, 11-30
- Sonic velocity**, 15-28
- Soot blowers for economizers**, 7-33
- Source**, plane, of neutrons, 17-09  
point, of neutrons, 17-08
- Source and sink distribution**, 5-09
- Space requirements**, boiler, 7-06  
refrigerated goods (Table), 11-43  
turbine, 8-94
- Span of thermometers**, 18-06
- Spark plugs**, aircraft engine, 13-49
- Specific fuel consumption**, engine (def), 13-45
- Specific gravity**, aviation fuel, 13-50 (*see also name of substance*)  
butane, 2-60  
dry gas, 2-75  
ethanol, 2-59  
gas, wet basis, 2-75  
gasoline, 2-59  
kerosene, 2-59  
oils, 2-47  
propane, 2-60  
wood, 2-40
- Specific heat**, 3-03  
air, high pressures, 3-59  
variation with temperature, 3-59  
butane, 2-60  
chemical elements (Table), 3-04  
at constant pressure, air, 1-03  
at constant volume, air, 1-03  
determination, 3-03  
effect of pressure, 1-06  
fuel oils, 2-48
- Specific heat** (*continued*)  
gases (Tables), 3-05, 3-54, 3-58  
gasoline, 2-59  
kerosene, 2-59  
liquids (Table), 3-05  
mixtures, 3-54  
molar, 2-98  
of gases, 2-10  
propane, 2-60  
sodium chloride solutions, 3-06  
solids (Table), 3-06  
substances, 3-03  
vapors (Table), 3-05
- Specific heat ratio**, air, 1-03  
gases (Tables), 3-05, 3-54  
vapors (Table), 3-05
- Specific humidity**, 1-07
- Specific output of typical internal-combustion engines** (Tables), 13-17, 13-18, 13-19
- Specific speed**, hydraulic turbine runner, 5-24  
pump, 5-51  
selection of, for pumps, 5-53
- Specific volume**, ammonia solutions (Table), 11-34  
gasoline, 2-59  
kerosene, 2-59  
saturated air (Table), 9-06
- Specific weight**, typical internal-combustion engines (Tables), 13-17, 13-18, 13-19
- Specifications**, aviation fuel, 13-50  
coal, 2-24  
diesel fuel oil, 13-32  
flange material, 6-04  
fuel oil, 2-46  
valve material, 6-04
- Speed**, boiler-feed pump, 7-42 (*see also Speeds*)  
internal combustion engine (Tables), 13-17, 13-18, 13-19  
locomotive diameter, 14-11  
maximum, of airplanes, 15-17  
propagation of flame, 2-69  
stalling, airplane, 15-17
- Speed/length ratio**, ships, 15-71
- Speed measurements**, 19-04
- Speed ranges**, airplane power plants, 15-19
- Speed ratings**, 60-cycle generator, 16-16
- Speed regulation**, hydraulic turbine, 5-43
- Speed-tractive effort characteristics**, locomotive, 14-30
- Speeds**, belted exciter (Table), 16-17 (*see also Speed*)  
critical, 8-36  
generator synchronous, 5-27  
power pump (Table), 5-73  
turbine, 8-12
- Spheres**, drag of, 15-14  
geometry of, 20-60
- Spheroids**, geometry of, 20-61
- Spillways**, submerged, 5-18
- Spinning reserve** (def), 16-100
- Splash surface**, cooling tower, 9-28
- Spontaneous combustion**, 2-33
- Spray cooler**, 9-22
- Spray ponds**, 9-29  
average final temperatures (Table), 9-29  
nozzle pressures, 9-30
- Spreader stokers**, 7-70  
air requirements, 7-71  
boiler capacity range, 7-05  
cinder losses, 7-71  
coals used, 7-71  
combustion rates, 7-04, 7-71  
with continuous-ash-discharge grates, 7-70  
dumping grates, 7-70

- Spreader stokers** (*continued*)  
 fly ash from, 7-93  
 furnace design, 7-71  
 heat-release rates, 7-75  
 manufacturers, 7-71  
 with stationary grates, 7-70
- Springs**, deflection of semi-elliptic, 14-80
- Square**, geometry of, 20-55
- Square roots of numbers**, 20-27
- Squares of numbers**, 20-27
- Stability**, aircraft, 15-22  
 aircraft, criterion of longitudinal, 15-22  
   directional, 15-23  
   lateral, 15-23  
 compressor (def), 10-39  
 of control, 18-30  
 longitudinal, aircraft, 15-22
- Stability limit**, axial-flow compressor, 10-39
- Stage**, impulse, 8-02  
 turbine, 8-03
- Stalling speed**, airplane, 15-17
- Standard atmosphere** (Table), 15-06
- Standard specific weight**, atmospheric air, 15-06
- Standards**, diesel engine, 13-14  
 diesel governor, 13-16  
 fan, 1-58  
 fitting dimensional, 6-05  
 flange dimensional, 6-05  
 valve dimensional, 6-05
- Star-delta transformer connections**, 16-71
- Star-star transformer connections**, 16-70
- Starting**, of gas turbine power plant, 15-50  
 of gas turbines, 10-45
- Starting characteristics**, automotive engine, 14-74
- State**, characteristic equation of, 3-53  
 equation of, 5-02  
 properties of, partial derivatives, 3-55
- State-line**, turbine, 8-63, 8-68
- Static balance**, 8-39
- Static pressure holes**, 19-10
- Stationary grates**, boiler capacity range, 7-05  
 combustion rate, 7-04
- Stayblade material**, 15-52
- Steady-flow process**, 3-51
- Steam**, condition of exhaust, 4-08  
 enthalpy, 4-02  
 equation for flow of, 18-19  
 flow in nozzles, 8-17  
 low-pressure heating, pipe sizes, 12-32  
 moisture, 7-19  
 purity, 7-19  
 quality of wet, 4-08

- Weather conditions in North America** (Table), 9-24
- Weathering of coal**, 2-33
- Wedge**, geometry of, 20-59
- Weight**, aircraft structural material (Table), 15-05  
 brass pipe (Table), 6-32  
 butane, 2-60  
 copper bars (Table), 16-06  
 copper pipe (Table), 6-32  
 Everdur pipe (Table), 6-32  
 per foot, seamless tubing (Table), 6-31  
 internal-combustion engines (Tables), 13-17, 13-18, 13-19  
 measures of (Table), 20-45  
 metric equivalents (Table), 20-47  
 propane, 2-60  
 seamless steel pipe (Table), 6-26  
 seamless tubing (Table), 6-31  
 turbine, 8-94  
 water vapor per pound of dry air (Table), 9-05  
 welded pipe (Table), 6-26
- Weights and dimensions**, low-speed generators (Table), 16-19  
 high-speed generators (Table), 16-19
- Wetris, Cippioletti**, 5-20  
 equation for, 5-19  
 discharge over, 5-11  
 flow over, 5-18  
 measuring, 5-19  
 rectangular, 5-19  
 triangular notch, 5-20
- Welded pipe**, dimensions (Table), 6-25  
 weights (Table), 6-26
- Welding**, steel pipe, 6-24  
 pipe, 6-13  
 procedure, 6-14  
 stress relief, 6-14
- Welds**, butt, in pipe, 6-13  
 fillet, in pipe, 6-14  
 seal, in pipe, 6-14
- Wells**, thermometer, 18-07
- Westinghouse gas turbine**, 10-20, 10-29
- Westinghouse turbojet**, 15-66
- Wet-bottom furnaces**, 7-81
- Wet-bulb and dry-bulb temperature difference** (Table), 3-41
- Wet-bulb temperature**, 1-07, 12-74
- Wetness at turbine exhaust**, 8-70
- Wetted perimeter**, 1-32
- Wetted surface**, cooling tower, 9-28
- Weymouth equation for flow**, 1-31
- Wheat**, heating value, 2-44
- Wheel arrangement**, diesel locomotive, 14-31  
 electric locomotive, 14-47
- Wheel efficiency**, impulse turbine, 8-26
- Wheelbase**, of buses, 14-61  
 light cars, 14-61
- Wheels**, fan, 1-73  
 locomotive, 14-56
- Whyte system**, electric locomotive classification (Table), 14-47
- Willans line**, for turbines, 8-63
- Williams and Hazen's equation for water flow**, 5-16
- Wilson limit**, supersaturation, 8-18
- Wind**, in U. S. cities (Table), 12-02
- Wind conditions in North America** (Table), 9-24
- Wind velocity for cooling towers**, 9-24
- Windlass**, anchor, 15-82
- Windows**, infiltration through (Table), 12-10
- Wing loading**, airplane, 15-17
- Wings**, rotating, jet propulsion of, 15-42
- Wire**, electric, 16-73
- Wire gage**, American, 16-08
- Wire gages** (Table), 16-08
- Wires**, drag of, 15-15
- Wiring**, for diesel engines, 13-21  
 general plant, 16-74  
 underground, 16-74
- Witte diesel engine**, 13-17
- Wood**, combustion flue-gas analysis (Table), 2-41  
 combustion properties, 2-40  
 composition (Table), 2-40  
 heating value (Table), 2-40  
 specific gravity, 2-40  
 thermal conductivity, 11-37, 12-05, 12-09  
 weight per cord (Table), 2-40
- Wool**, thermal conductivity, 3-14
- Work** (def), 3-50  
 dimensions, 5-05  
 metric equivalents, 20-49
- Work ratio**, gas turbine, 10-11
- Wright Aeronautical Corporation propjet**, 15-68
- Wright engines**, 15-54
- Wrought-iron pipe**, 6-02  
 dimensions (Table), 6-27  
 weights (Table), 6-28
- X-40 alloy (cast)**, composition, 10-35
- Xenon**, nuclear properties, 17-19
- Yield point**, pipe material, 6-03  
 tube steel (Table), 6-29
- Yttrium**, nuclear properties, 17-18
- Zeolite**, 7-59
- Zeolite water softener**, capacity, 7-59  
 equations, 7-58  
 pH value, 7-59  
 regeneration of, 7-58
- Zero pressure gas properties**, 3-58
- Zeta function**, Gibbs', 3-55
- Zinc**, emissivity, 3-21  
 nuclear properties, 17-18  
 thermal conductivity, 3-14
- Zirconium**, nuclear properties, 17-18
- Zone**, spherical, geometry of, 20-61
